# Structures and Stabilities of Endohedral Fullerenes Containing Lanthanides and Actinides 

## T H E S I S

Submitted by

## Sara Elizabeth Pérez Figueroa

In partial fulfillment of the requirements for the degree of
Doctor in Science

In

Nanosciences and Nanotechnology

Advisors:
Dra. Patrizia Calaminici
Dr. Andreas M. Köster

El presente trabajo se realizó en el área de Química Teórica del Departamento de Química del Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional (Cinvestav-IPN), bajo la dirección de la Prof. Dra. Patrizia Calaminici y del Prof. Dr. Andreas M. Köster, dentro del Programa de Doctorado de Nanociencias y Nanotecnología; y con el apoyo de la beca No. 377712 y el proyecto No. 252658 otorgados por el Consejo Nacional de Ciencia y Tecnología (CONACyT).

Los recursos computacionales fueron provistos por el Laboratorio Nacional de Cómputo de Alto Desempeno a través de Xiuhcóatl, ABACUS: Laboratorio de Matemática Aplicada y Cómputo de Alto Rendimiento del Departamento de Matemáticas y por la infraestructura de la sección de Química Teórica del Departamento de Química del Cinvestav.

## Acknowledgments

I would like to express my gratitude to Dr. Patrizia Calaminici and Dr. Andreas Köster for valuable discussions and support through this scientific research. Both provided me much needed computational facilities. Thanks for giving me the opportunity to be a part of Theoretical Chemistry Group.

Many thanks to Dr. Gerald Geudtner, for the collaboration and always taking the time to go through and suggest improvements wherever needed in my work. It was fun working with you.

For undertaking the unenviable task of serving on my thesis committee I gratefully acknowledge to Dr. Luis E. Sansores Cuevas, Dr. Isaac Hernández Calderón, Dr. Miguel García Rocha, and Prof. Shiv Khanna. All have made valuable contributions and suggestions when they were sorely needed.

I gratefully acknowledge the guidance and help of former members of the Theoretical Chemistry Group in Cinvestav. They taught me with great dedication and patience my first (and many times not-so-first) understandings of the quantum realm. Thanks to Dr. Bernardo Antonio Zuñiga Gutiérrez, Dr. Daniel Mejía Rodríguez and Dr. Rogelio Isaac Delgado Venegas.

For my buddies of the Theoretical Chemistry Group in Cinvestav. Their discussions, insight and merriment have sustained me during this arduous trek.

Thanks to the Nanosciences and Nanotechnology Program as well as to the Chemistry Department. It has been an honor to receive classes in these two programs.

Financial support from the CONACyT Ph.D. Fellowship No. 377712 is gratefully acknowledged.

## Dedicatoria

- A mi amada familia: Mis padres, Francisco Pérez Soto y Esther Figueroa Hernández; mis hermanas Rebeca Alejandra y Carolina Esther Pérez Figueroa. Gracias por ser los guardianes de mi cordura durante todos estos años. Siempre han sido mi apoyo, aliento y la fuente de innumerables ejemplos a seguir. Así pues, esto es para ustedes que me han ayudado a mantener el ritmo: "Con ustedes todo, sin ustedes nada".
- A Diego. Por el cariño y apoyo brindado. Tengo mucha suerte de tenerte a mi lado, contigo siempre he podido hablar sobre mi trabajo de investigación y pedir consejos en tiempos problemáticos.
- A mis amigos, a los que me han acompañado a través de los tiempos y a los que fui ganando durante mi estancia en Cinvestav. Ustedes han sido grandes aliados y cómplices que me han ayudado en formas que van más allá de la investigación y lo académico.

## List of Figures

Figure 2.1: Geodesic dome designed by the architect R. Buckminster Fuller (top), a soccer ball that resembles the $\mathrm{C}_{60}$ structure (bottom-left); and the $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ (bottom-right).
Figure 2.2: Number of isolated pentagon rule (IPR) isomers versus fullerene size from $\mathrm{C}_{60}$ to $\mathrm{C}_{96}$ (Image taken from ref. [5]).
$\begin{array}{ll}\text { Figure 2.3: } & \begin{array}{l}\text { Schematic representation of orbital hybridizations for the planar 6,6,6 C } \\ \text { atoms (left), compared to the curved } 6,6,5 \mathrm{C} \text { atoms (right) (Image taken }\end{array} \\ & \text { from ref. [38]) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . } 14\end{array}$
Figure 2.4: Different fused pentagon patterns that can be found in non-IPR isomers. Double fused pentagons (left), triple directly fused pentagons (middle), and triple sequentially fused pentagons (right) (Image taken from ref. [44]). 15
Figure 2.5: Periodic table of endohedral elements, successfully used in the synthesis of endofullerenes by arc-discharge, laser ablation or implantation. . . . . 17
Figure 2.6: Different approaches to synthesize endohedral fullerenes. (i) Encapsulation during the fullerene formation such as in laser ablation or arcdischarge methods. (ii) Encapsulation into already available empty fullerene; typical variants are implantation (through ion beam or high pressure-high temperature treatment) and molecular surgery (encapsulation is achieved in a series of chemical reactions opening and closing the carbon cage). Image taken from ref. [51].

Figure 3.1: The dodecahedron (solid lines) and its dual, the icosahedron (dotted lines). 26
Figure 3.2: Planar embeddings of fullerene graph (black lines represent edges and red points vertices) and its dual (blue lines represent edges and pink dots vertices), along with a 3D embedding of the dual for the $\mathrm{C}_{20}$ (Image partially taken from ref. [136])
Figure 3.3: Unwinding $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ and $\mathrm{C}_{70}\left(\mathrm{D}_{5 \mathrm{~h}}\right)$ into face spirals (Image partially taken from ref. [29])
Figure 3.4: Unfolding the icosahedron, the dual of the fullerene polyhedra $\mathrm{C}_{20}$. . . . 31
Figure 3.5: The Goldberg-Coxeter method for fullerene graphs with icosahedral symmetry. A superposition of an icosahedral net on a hexagonal tessellation determines the positions of hexagonal and pentagonal faces in a fullerene. The example shows the construction for a (1,1)-icosahedral fullerene, the $\mathrm{C}_{60}$

Figure 3.6: The (1, 1)-icosahedral net (a) assembled along with the hexagonal lattice etched onto its faces (b). The equilateral triangle repeat units that are used within the GC method to assemble the icosahedron of the $\mathrm{C}_{60}, \mathrm{C}_{80}$ and $\mathrm{C}_{240}$ icosahedral fullerenes32

Figure 3.7: The Stone-Wales transformation. . . . . . . . . . . . . . . . . . . . . . . 34
Figure 3.8: A hypothetical mechanism for expansion of a fullerene by a two carbon atom insertion.
Figure 3.9: Leapfrogging a dodecahedron: A dodecahedron is converted to a 32vertex deltahedron by capping, then to a truncated icosahedron by taking the dual.

Figure 4.1: Computational protocol designed in order to elucidate the structure of endohedral metallofullerenes. Empty cage (left), endohedral clusters (middle) and EMF system (right).
Figure 4.3: Relevant information extracted from the five generated FULLERENE outputs for the $\mathrm{C}_{78}$ fullerene cages.
Figure 4.4: Variation in the order of stability of $\mathrm{C}_{78}$ isomers as function of net charge. Each colored symbol represents the energy of a given isomer, in kcal/mol, relative to that of the most stable one for a given charge. To guide the eye, data points are connected by straight lines.

Figure 5.1: Representations of the $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ optimized structures listed in Table 5.10.

Figure 5.2: Differences in carbon atom charges and C-C bond valences between the optimized empty $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ cage and the one with the uranium atoms enclosed. Blue represents gain in either charge or bond valences while red represents loss. The size of the circles and the thickness of the lines are proportional to this gain or loss.
Figure 5.3: Bond lengths distribution. Dashed lines represent the two different CC bonds in a perfect artificial icosahedral $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ empty cage while dotted lines are the same but for the hexaanionic one. Both, dashed and dotted black lines, correspond to a $[6,6]$ bond (a bond shared between two hexagons) and magenta lines to a [6,5] bond (a bond shared between a hexagon and a pentagon).
Figure 5.4: Simulated IR (top) and Raman (bottom) spectra for $\mathrm{U}_{2} @ \mathrm{C}_{80}$ structures $S_{1}$ and $S_{2}$ (inset: IR spectrum from 0-160 $\mathrm{cm}^{-1}$ ). . . . . . . . . . . . . . 88

## Abstract

A study on the geometric and electronic structure of endohedral metallofullerenes containing lanthanides and actinides within the framework of auxiliary density functional theory (ADFT) is presented in this thesis. The main objective of this work was to reveal the possible molecular structures of $\mathrm{U}_{2} \mathrm{C}_{79}$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ endometallofullerene (EMF) systems observed by mass spectrometry analyses. In order to achieve this major goal, an efficient computational strategy that was successfully employed to obtain insight into the structures of these two EMFs is presented. Calculations of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system were performed and compared with experimental and theoretical characterizations recently published, in order to assess and validate our proposed theoretical methodology. Our studies show that the ADFT approach together with the GEN-A2** auxiliary function set is suitable for uranium and lutetium calculations. For the carbon atoms in the studied EMFs the GEN-A2* auxiliary function set yields converged results. With the here proposed ADFT composite approach, consisting of GGA structure optimizations and hybrid single-point energy calculations, accurate and reliable relative energies for middle- and large-sized fullerene isomers have been achieved.

Herein, we report two different configurations of $U$ ions in the $U_{2} @ C_{80}$, where the $D_{2 h}$ structure is more stable than the $\mathrm{C}_{\mathrm{i}}$ structure by $0.08 \mathrm{kcal} / \mathrm{mol}$. Indicating with this, a flat potential energy surface of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF system, allowing thus, the U movement from one configuration to another, which is in agreement with the chrystallographic data which reveal that the U positions are disordered inside the fullerene cage. For the $\mathrm{U}_{2} \mathrm{C}_{79}$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ EMFs, the structural assumptions were based on the consideration of metal-carbon clusters comprising two or three metal atoms ( U or Lu , as appropriate) and one or three carbon atoms inside the fullerene cages. From our $\mathrm{U}_{2} \mathrm{C}_{79}$ calculations, the $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ structure is predicted to be $84.02 \mathrm{kcal} / \mathrm{mol}$ lower in energy than the $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ structure. Thus, the $\mathrm{U}_{2} \mathrm{C}^{( } \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}^{-}}\right.$ 24109) is assigned as the possible molecular structure for this carbon-containing EMF. On the other hand, for the $\mathrm{Lu}_{3} \mathrm{C}_{107}$, two low-lying structures, the $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}\left(\mathrm{C}_{1}-735\right) \text { and }}$ $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}\left(\mathrm{D}_{2}-821\right)$, within an energy window of only $0.80 \mathrm{kcal} / \mathrm{mol}$ were found. Last, with the aim to gain more insight into the endometallofullerene systems here studied, the infrared and Raman spectra were simulated for relevant minimum structures. The obtained
results indicate that the simulated Raman spectra can be used as finger print to distinguish between isomers and therefore to guide future experiments.

## Resumen

En esta tesis se presenta un estudio sobre la estructura geométrica y electrónica de metallofullerenos endohedrales que contienen lantánidos y actínidos en el marco de la teoría del funcional de la densidad auxiliar (ADFT). El objetivo principal de este trabajo fue revelar las posibles estructuras moleculares de los sistemas $\mathrm{U}_{2} \mathrm{C}_{79}$ y $\mathrm{Lu}_{3} \mathrm{C}_{107}$ observados mediante análisis de espectrometría de masas. Para lograr este objetivo, se presenta una estrategia computacional eficiente empleada con éxito para obtener información sobre las estructuras de estos dos metallofullerenos. Con el fin de evaluar y validar nuestra metodología teórica se realizaron cálculos del sistema $\mathrm{U}_{2} @ \mathrm{C}_{80}$ y se compararon con las caracterizaciones experimentales y teóricas publicadas recientemente. Nuestros estudios muestran que el enfoque ADFT a la par con el conjunto de funciones auxiliares GEN-A2** es adecuado para el estudio de uranio y lutecio. Para los átomos de carbono en los fullerenos de metales endohedrales estudiados, el conjunto de funciones auxiliares GEN-A2* produce resultados convergentes. Con la metodología ADFT compuesta, propuesta aquí, que consiste en optimizaciones GGA de estructura y cálculos de energía híbridos de un solo punto, se han logrado energías relativas precisas y confiables para isómeros de fullerenos de tamaño mediano y grande.

En este trabajo, nosotros reportamos dos configuraciones diferentes para los iones U en el $\mathrm{U}_{2} @ \mathrm{C}_{80}$, donde la estructura $\mathrm{D}_{2 \mathrm{~h}}$ es más estable por $0.08 \mathrm{kcal} / \mathrm{mol}$ que la estructura $\mathrm{C}_{\mathrm{i}}$. Indicando con esto una superficie de energía potencial plana del sistema $\mathrm{U}_{2} @ \mathrm{C}_{80}$, permitiendo el movimiento de U de una configuración a otra, lo cual se encuentra en concordancia con los datos cristalográficos que revelan que las posiciones de los átomos de U están desordenadas dentro del fullereno. Para los sistemas $\mathrm{U}_{2} \mathrm{C}_{79}$ y $\mathrm{Lu}_{3} \mathrm{C}_{107}$ las suposiciones estructurales se basaron en la consideración de compuestos de metal y carbono que comprenden dos o tres átomos de metal ( U o Lu, según corresponda) y uno o tres átomos de carbono dentro de los fullerenos. A partir de nuestros cálculos de $\mathrm{U}_{2} \mathrm{C}_{79}$, se predice que la estructura $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ es $84.02 \mathrm{kcal} / \mathrm{mol}$ más estable en energía que la estructura $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$. Por lo tanto, $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ se asigna como la posible estructura molecular para este EMF. Por otro lado, para el $\mathrm{Lu}_{3} \mathrm{C}_{107}$, se revelaron dos estructuras de mínima energía, $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}\left(\mathrm{C}_{1}-735\right) \text { y }}$
$\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}\left(\mathrm{D}_{2}-821\right)$, dentro de una ventana de energía de sólo $0.80 \mathrm{kcal} / \mathrm{mol}$. Por último, con el objetivo de obtener más información sobre los sistemas de fullerenos de metales endohedrales aquí estudiados, se simularon los espectros infrarrojo y Raman para las estructuras estables relevantes. Los resultados obtenidos indican que los espectros Raman simulados pueden ser usados como picos característicos para distinguir entre los isómeros y por lo tanto poder guiar futuros estudios experimentales.

## Chapter 1

## Introduction and Objectives

The discovery of fullerenes more than three decades ago initiated a vastly expanding research field [1-8]. The first synthesized and still the most stable and abundant fullerene $\mathrm{C}_{60}$, has the shape of a football ball. It is also called Buckminsterfullerene, named after the architect Buckminster Fuller, whose designs resemble the structure of the fullerenes [5]. The definite breakthrough, that started off fullerene chemistry, was accomplished by Krätschmer and Huffman when they isolated solid $\mathrm{C}_{60}$ [9].

The hollow internal space of fullerene molecules is suitable for encapsulating a wide range of atoms, molecules and even otherwise unstable species including clusters. We call these molecules endohedral fullerenes. These are also called endofullerenes or, when it is a metal atom or metallic system that is encapsulated, endohedral metallofullerenes (EMFs) [7]. The fist example of EMFs, was the mass signal of $\mathrm{La} @ \mathrm{C}_{60}$, observed by Smalley and coworkers soon after their discovery of the famous $\mathrm{C}_{60}[10]$. However the first isolated endohedral fullerene was $\mathrm{La}_{\mathrm{Q}} \mathrm{C}_{82}$ [11]. Due to the large variety of metals that can be used to make endohedral fullerenes, these nano-materials are expected to be multifunctional. Actually, electron transfer from the inside metal to the outer fullerene cage drastically alters the electronic properties of fullerenes. Thus, EMFs offer a broad range of properties of potential use in different fields such as materials science, photovoltaics and biomedicine [5-8].

The interest in endohedral fullerenes encapsulating lanthanide ions is related to the unfilled 4 f shell of the lanthanide ions, which gives rise to large magnetic moments and a variety
of interesting magnetic properties. Also, these materials have a great potential for applications as contrast agents for magnetic resonance or X-ray investigations, biological tracing agents, and radiopharmaceuticals [12-14]. Up to now, except for a few cases, work in endohedral fullerenes field has mostly focused on the lanthanide based EMFs, given their relatively easy synthesis and high product yield [15, 16]. In sharp contrast, the experimental reports on the actinide EMFs are scarce due to their rather low yield, resulting in that our understanding of actinide EMFs lags behind that of their lanthanide counterparts [17-20]. Compared with the core-like lanthanide 4 f orbitals, early actinide elements feature spatially extended and easily promoted 5 f orbitals and thus could provide more accessible valence electrons for chemical bonding, suggesting potentially new EMF electronic structures and cage isomer preferences for the actinides [21]. Early actinides from thorium to curium, which possess much richer valence states and more complicated electronic structures compared to their lanthanide analogues, have also been encapsulated into fullerene cages, motivated by their potential application in the field of nuclear medicine [17-20, 22, 23]. Other actinide EMFs are only studied by theoretical calculations. In particular, recent computational studies predicted unexpected actinide metal-metal bonds and unique cage structures for uranium-based EMFs [24, 25]

Once new EMFs have been synthesized and then characterized by mass spectrometry, the structure elucidation through experimental techniques such as X-ray diffraction (in combination with other techniques) is the final and conclusive step for the precise determination of the isomeric structure of the carbon cages. However, the low yield obtained in synthesis and difficulties in the isolation process, are the major obstacle that causes struggles in the experimental structural assignment. For these reasons the combination of extensive theoretical studies along with experimental analysis, is a powerful tool to achieve a correct and complete elucidation of the structure, which includes, the determination of the fullerene isomer as well as the geometry and position of the inner cluster. Here we present an efficient computational strategy that was successfully employed throughout this work to obtain insight into the geometrical and electronic structure of the recently produced $\mathrm{U}_{2} \mathrm{C}_{79}$ [26, 27] and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ [28] endohedral metallofullerenes.

The thesis is organized in the following way. In Chapter 2 a preamble of the fullerene world, from the discovery of this new family of molecules to the potential applications that they have is presented. This preamble contains a short description of the discovery of the first fullerene, the most interesting properties of these carbon molecules, and some of the interesting aspects that are crucial for their study: the mathematical definition, enumeration, nomenclature, properties and different types of fullerenes. Chapter 3 describes briefly some topological methods for the construction of all possible fullerene isomers employed by the two most common fullerene generation programs. In this chapter, also the theoretical method used in this thesis, is described. The Kohn-Sham method and the linear combination of Gaussian-type orbital (LCGTO) approximation for the solution of the Kohn-Sham equations and the foundation of ADFT, are outlined. In Chapter 4 a description step-by-step of the designed computational strategy is addressed. The methodology validation for the theoretical study of endohedral metallofullerenes, based on calculations of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system, is presented in Chapter 5. In Chapter 6 and 7 applications of the computational methodology to elucidate the structures of the $\mathrm{U}_{2} \mathrm{C}_{79}[26,27]$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}[28]$ systems, respectively, are presented. Finally, in Chapter 8 the most relevant results of the former chapters are summarized. The resulting perspectives of this work are also given in the last chapter. In the appendices, tables of the complete set of optimized isomers of the $\mathrm{C}_{78}, \mathrm{C}_{104}$ and $\mathrm{C}_{106}$ fullerene cages at the PBE/DZVP/GEN-A2* level of theory, are reported, too.

The main objective of this work is to elucidate the structures of the $\mathrm{U}_{2} \mathrm{C}_{79}$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ endohedral metallofullerene, observed by mass spectrometric analysis [26-28], employing the deMon2k program. In order to achieve this goal, we proposed the following specific objectives:

- Understand the key factors that govern the stabilization of EMFs and based on that, design a computational strategy in order to be able to characterize new EMFs systems.
- Elucidate the methodology with the best performance for the fullerene cage calculations.
- Elucidate the appropriate methodology for the description of the endohedral element(s) (lanthanides/actinides based clusters).
- Validation and application of the computational strategy and methodology for the structure elucidation of the $\mathrm{U}_{2} \mathrm{C}_{79}$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ endohedral metallofullerenes.

## Chapter 2

## Fullerenes and Endohedral Fullerenes

### 2.1 Fullerene Cages

### 2.1.1 Buckminsterfullerene

In the 70's Osawa, Bochvar and Gal'pern theoretically discussed the possibility of the existence of polyhedral carbon clusters [1-3]. However, it was not until the late 1980s that Smalley, Kroto and Curl obtained cold carbon clusters, when they carried out an experiment to simulate the condition of red giant stars formation. In the recorded mass spectrum, they found a large peak ( $720 \mathrm{~m} / \mathrm{z}$ ) commensurate with 60 carbon atoms [4]. This $\mathrm{C}_{60}$ carbon cluster was proposed to possess a closed cage structure which resembles a soccer ball. Such a structure is called "Buckminsterfullerene" (see Figure 2.1) in honor of the geodesic domes designed with pentagonal and hexagonal structures by the architect Buckminster Fuller [5].

The 1996 Nobel Prize in Chemistry was awarded to Kroto, Curl and Smalley for their discovery of fullerenes. In 1990, Huffman and Krätschmer designed a method in order to obtain large scale quantities (grams) of fullerenes [9], thus leading to the functionalization of these carbon spheres and the development of new and sophisticated structures. Since then these new carbon allotropes have received significant attention from numerous research groups that have extensively studied them with the aim of determining the most stable structures as
well as their properties and the use of their derivatives, either in materials science or medical applications [5-8].

Figure 2.1: Geodesic dome designed by the architect R. Buckminster Fuller (top), a soccer ball that resembles the $\mathrm{C}_{60}$ structure (bottom-left); and the $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ (bottom-right).

### 2.1.2 Definition of Fullerenes, Enumeration and Nomenclature

The International Union of Pure and Applied Chemistry (IUPAC) defines a fullerene as a "compound composed solely of an even number of carbon atoms which form a cage-like fused-ring polycyclic system with twelve five-membered rings and the rest six-membered." In practice, all other closed-cages structures built from three-coordinated carbon atoms are also called fullerenes. These closed-cage structures comprised of five- and six-membered rings resulting in a bonding framework, can be seen as polyhedrons in which a carbon atom is located at each vertex, a bond along each edge, and a ring on each face. Because of their geometrical nature, fullerenes are polyhedrons and, therefore, they follow Eulers theorem which states that for a given polyhedron the number of vertices $(n)$, edges $(e)$, and faces $(f)$ are related by [29]:

$$
\begin{equation*}
n-e+f=2 \tag{2.1}
\end{equation*}
$$

### 2.1. FULLERENE CAGES

Each carbon atom in a fullerene is bonded to three other atoms. Therefore, for a $\mathrm{C}_{n}$ fullerene (where $n$ is an even integer) the number of edges is $e=3 n / 2$, which, by Eq. (2.1) yields the number of faces $f=n / 2+2$. Since all the pristine fullerenes that have been isolated and characterized to date possess only five- and six-membered faces (it is possible to obtain fullerenes with four- or seven-membered rings only by chemical modifications [30-32]) one can calculate the number of vertices and faces through the number of pentagons $(p)$ and hexagons ( $h$ ),

$$
\begin{equation*}
5 p+6 h=3 n \tag{2.2}
\end{equation*}
$$

and the total number of faces is:

$$
\begin{equation*}
p+h=\frac{n}{2}+2 \tag{2.3}
\end{equation*}
$$

Inserting these two equations into Eq. (2.1) yields $p=12$ and $h=n / 2-10$. There is at least one such fullerene polyhedron for each even number of vertices $n \geq 20$, with the sole exception of $n=22$. Experimentation with models soon reveals that it is impossible to construct a 22-vertex polyhedron with 12 pentagons and a single hexagon. Odd numbers of vertices are also precluded for all trivalent polyhedra, including fullerenes, because the number of edges $e=3 n / 2$ must be an integer. The smallest fullerene polyhedron is the dodecahedron, which is the only fullerene with $n=20$ vertices [29].

The number of distinct fullerene isomers that can be constructed for a given number of carbon atoms increases rapidly beyond $n=24$, giving rise to the problem of generation (construction) and, of course, systematic enumeration of all possible isomers [29]. This problem was solved for all practical fullerene sizes ( $n<380$ ) by Fowler and Manolopoulos, who proposed the spiral algorithm [29, 33], which will be discussed in detail later in Chapter 3. This algorithm was the first to construct a list of fullerenes by enumerating all possible isomers as they were generated by the code [29, 33]. The nomenclature for fullerene cages proposed by the IUPAC, states that the "fullerenes shall be named with the number of carbons in the molecule being indicated in square brackets before the word "fullerene", followed by the point group symmetry, and where necessary due to degeneracy i.e. fullerenes with the same point-
group symmetry, subdivision by means of capital Roman numerals (in parentheses), assigned on the basis of the lowest numeral sequence at the first point of difference in the ring spiral, using the ones given in the Atlas of Fullerenes" [34]. For instance, two isomers of the 78 carbon atoms cage with the same point-group symmetry, would have the following IUPAC names: [78- $\left.\mathrm{C}_{2 \mathrm{v}}(\mathrm{I})\right]$ fullerene and [78- $\left.\mathrm{C}_{2 \mathrm{v}}(\mathrm{II})\right]$ fullerene. However, the most commonly used and widely accepted nomenclature is the one using the spiral code number, that is, the sequential number of the isomer in the list generated by the spiral algorithm, and the symmetry of the cage. Thus, our previous example would now be $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24106\right)$ and $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24107\right)$.

### 2.1.3 The Isolated Pentagon Rule and Steric Strain

Based on the available methods to produce fullerenes, it is concluded that the most abundant fullerene is the $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}-1812\right)$ and is followed by $\mathrm{C}_{70}\left(\mathrm{D}_{5 \mathrm{~h}}-8149\right)$ [35]. In fact, these two isomers are the only ones among all the possible structures of $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ (1812 and 8149, respectively), with the peculiarity of having its pentagons isolated by hexagons. The above mentioned, together with the great stability that possess the corannulene molecule (a molecule that consist of a cyclopentane ring surrounded by 5 benzene rings), suggested that a structure in which pentagons are completely surrounded by hexagons is more stable than one where two or more pentagons are next to each other [36]. These considerations gave rise to the so-called isolated pentagon rule (IPR) proposed by Kroto and Schmalz et al. [36, 37] which states that the most stable fullerene isomers will have, where this is possible, all 12 pentagons isolated from one another by intervening hexagonal rings. Fullerenes that fulfill this rule are called IPR isomers, while those with adjacent pentagons in their structures are called non-IPR isomers.

The isolated pentagon rule can be used as a criterium to assess the relative stabilities of fullerene isomers. The importance of the IPR can be appreciated when all possible isomers for a given fullerene (e.g. 31924 isomers are possible for $\mathrm{C}_{80}$ ) have to be taken into account for its structure elucidation. To assist with this problem, the isolated pentagon rule has been employed as a tool to help to reduce the number of isomers that should be considered for

### 2.1. FULLERENE CAGES

the determination of the most appropriate structure [5, 6]. The IPR rule was also crucial to explain the larger abundances found in the experiments for the $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$ isomers, which are the first two fullerene cages that obey the isolated pentagon rule. Indeed, the rule is strictly followed by all experimentally available empty fullerenes. As Figure 2.2 shows only one IPR isomer exist for $\mathrm{C}_{60}$ and $\mathrm{C}_{70}$. However, for larger fullerenes the number of possible IPR isomers increases rapidly with the cage size [6].

Figure 2.2: Number of isolated pentagon rule (IPR) isomers versus fullerene size from $\mathrm{C}_{60}$ to $\mathrm{C}_{96}$ (Image taken from ref. [5]).

A way to justify the IPR consist in using the rehybridization ideas which imply that cages without fused pentagons are expected to reduce curvature and to have higher resonance energy [37]. The formal hybridization state of carbon in fullerenes is $s p^{2}$. Thus, carbon atoms should be planar with three neighboring carbon atoms in the same plane. From the geometrical point of view, planarity is achieved when a carbon atom is located on the fusion of three hexagons (see Figure 2.3). In this case, the $p_{z}$-orbitals of the neighboring atoms are exactly parallel and the optimal $\pi$-overlap of these orbitals is achieved. However, one cannot build fullerenes only from hexagons. Pentagons are necessary to create closed-cage structures. The carbon atoms in pentagons are no longer planar (the smaller angle of $108^{\circ}$ in pentagons vs $120^{\circ}$ in hexagons has to be compensated by the out-of-plane shift of the
central atom), which results in a $s p^{3}$-like hybridization (see Figure 2.3). In fact, deviation from planarity introduces strain energy and partially destroys the $\pi$-overlap between adjacent carbon atoms, decreasing the aromaticity of fullerenes [38, 39]. Schmalz explained that a pair of fused pentagons creates a region of resonance destabilized antiaromaticity in violation of Hückel's $4 n+2$ rule [37, 40].

Figure 2.3: Schematic representation of orbital hybridizations for the planar 6,6,6 C atoms (left), compared to the curved $6,6,5 \mathrm{C}$ atoms (right) (Image taken from ref. [38]).

Pentagon adjacency is a major destabilizing factor in fullerene cages due to enhanced steric strain and resonance destabilization pertaining to the pentalene-type $8 \pi$-electron system $[37$, 40, 41]. Calculations of the pentagon-pentagon penalty (destabilizing energy) give values ranging from 16 to $35 \mathrm{kcal} / \mathrm{mol}$ per adjacency, depending on the level of theory used in calculations and the specific fullerene size treated [42, 43]. The isomers that present fused pentagons in the structure, i.e., the non-IPR isomers, are usually classified regarding the number of adjacent pentagon pairs (APPs) present in the carbon framework. The pentagon adjacencies can be arranged in several ways within the carbon cage as it is shown in Figure 2.4 [44].

Once introduced, the concept of IPR isomers and their counterparts, non-IPR isomers, give rise to two types of enumerations that are widely used to label cage isomers of fullerenes. Usually, a short form of numbering system is used, in which only the isomers that fulfill the isolated pentagon rule (IPR) are numbered. Whereas, for non-IPR isomers, the extended notation, which includes all possible isomers for a given number of carbon atoms, is used. For example, the $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24107\right)$ IPR isomer in the extended notation will be labeled as

### 2.2. ENDOHEDRAL METALLOFULLERENES

Figure 2.4: Different fused pentagon patterns that can be found in non-IPR isomers. Double fused pentagons (left), triple directly fused pentagons (middle), and triple sequentially fused pentagons (right) (Image taken from ref. [44]).
$\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-5\right)$ in the short notation, while for non-IPR isomers, the extended notation will always be used. From now on in this thesis, we use this twofold numbering system together with the fullerene notation aforementioned, which is de facto employed in many publications.

### 2.2 Endohedral Metallofullerenes

One attractive property of fullerenes, intrinsic to their closed-cage structure, is that they possess an inner space available for the encapsulation of atoms and clusters to form a new class of "hostguest" molecule. In particular, when the encapsulated species are metal atoms or metallic clusters, the formed carbon-metal hybrid molecules are referred to as endohedral metallofullerenes (EMFs) [7, 45, 46]. The first idea of these structures was conceived in 1985. Soon after the earliest experimental observation of the soccerball-shaped $\mathrm{C}_{60}$, the same research group also observed the molecular ion peak of $\mathrm{LaC}_{60}$ in a mass spectrum and concluded that a La atom might be encaged within the $\mathrm{C}_{60}$ [10]. This was the first proposal based on experiments of the so-called endohedral metallofullerenes. It is noteworthy that, although several lanthan fullerenes $\left(\mathrm{La}_{2} \mathrm{C}_{2 n}, 2 \mathrm{n}=70,7484\right)$ were observed in the raw soot, only the $\mathrm{La}^{@} \mathrm{C}_{82}$ fullerene survived in solvent and was extractable by toluene. Actually, this endohedral metallofullerene was the first to be produced in macroscopic quantities in 1991 [11].

The term endohedral for fullerenes with other species in their inner space was first introduced in 1991 [47, 48] and originates from a combination of Greek $\varepsilon \nu \delta o \nu$ (endon-within)
and $\varepsilon \delta \rho \alpha$ (hedra-face of a geometrical figure). EMFs (as well as other kind of endohedral fullerenes) are denoted as $\mathrm{M}^{@} \mathrm{C}_{2 n}$ where the symbol @ is conventionally used to indicate that the left-marked atoms or clusters are encapsulated inside of the right-indicated fullerene cage [7, 11, 45, 46, 49]. The corresponding IUPAC nomenclature is, however, different from this commonly used $M @ \mathrm{C}_{2 n}$ notation. It is recommended by IUPAC that EMFs e.g., La@ $\mathrm{C}_{82}\left(\mathrm{C}_{3 \mathrm{v}^{-}}\right.$ 7) should be called [82- $\mathrm{C}_{3 \mathrm{v}}$ (II)]fullerene-incar-lanthanum and be written $i \mathrm{LaC}_{82}\left\{\mathrm{C}_{3 \mathrm{v}}(\mathrm{II})\right\}$ [34].

An intriguing feature of EMFs is the intramolecular electron transfer, which results in novel structures, unique properties, and potential applications of these hybrid molecules. The formal electron transfer that has been found to happen between the trapped unit and the carbon cage is determinant for the understanding of these new properties [8, 45, 46]. Also, due to the interaction between the inner moiety and the carbon cage, it is possible to synthesize and isolate cages that, when empty, are not obtained in experiments. It is worth mentioning that, depending on the type of cluster or atoms trapped in the cage, it is possible to obtain different cage isomers and even different cage sizes. Therefore, chemists can "play" with the experimental settings to obtain different cage isomers [38, 44, 46]. Although the formation mechanisms of EMFs remain somewhat unclear, it is commonly accepted that the endohedral metallic cluster and the surrounding cage are mutually depending on each other due to their strong electrostatic interactions [50].

Since their discovery several types of endohedral fullerenes have been successfully synthesized. Figure 2.5 shows the periodic table of endohedral elements that, until now, are able to form endohedral fullerenes [51].

Until 1999, EMFs were mostly formed with one to three metal atoms encapsulated in the carbon cage. In 1999, it was found that the presence of a small amount of nitrogen gas in the arc-burning reactor resulted in a new type of EMF, metal-nitride clusterfullerenes (NCFs) with the composition $\mathrm{M}_{3} \mathrm{~N}^{\mathrm{N}} \mathrm{C}_{2 n}(\mathrm{M}=\mathrm{Sc}, \mathrm{Y}$, $\mathrm{Gd}-\mathrm{Lu} ; 2 \mathrm{n}=68-96)$ [52-54]. In 2001 it was discovered that some "conventional" EMFs actually had $\mathrm{C}_{2}$ carbide units inside the cage. For example, $\mathrm{Sc}_{3} @ \mathrm{C}_{82}$ and $\mathrm{Sc}_{2} @ \mathrm{C}_{86}$ were shown to be $\mathrm{Sc}_{3} \mathrm{C}_{2} @ \mathrm{C}_{80}$ and $\mathrm{Sc}_{2} \mathrm{C}_{2} @ \mathrm{C}_{84}$, respectively [55, 56].

Figure 2.5: Periodic table of endohedral elements, successfully used in the synthesis of endofullerenes by arc-discharge, laser ablation or implantation.

Modifications of the EMF synthesis by using either reactive gas $\left(\mathrm{NH}_{3}, \mathrm{CH}_{4}, \mathrm{SO}_{2}, \mathrm{CO}_{2}\right)$ or solid chemicals added to the graphite electrode allowed the synthesis of new types of EMFs with endohedral sulfur, oxygen, CH, CN, and other units [51, 57, 58]. The metal-oxide clusterfullerenes, such as $\mathrm{Sc}_{4} \mathrm{O}_{2} @ \mathrm{C}_{80}$ and $\mathrm{Sc}_{4} \mathrm{O}_{3} @ \mathrm{C}_{80}$ were synthesized using copper nitrate as the source of oxygen [57], while the use of guanidinium thiocyanate afforded formation of sulfide cluster fullerenes $\mathrm{M}_{2} \mathrm{~S} @ \mathrm{C}_{82}(\mathrm{M}=\mathrm{Sc}, \mathrm{Y}, \mathrm{Dy}, \mathrm{Lu})$ [58]. Encapsulation of alkali metals within the carbon cage can be achieved either by laser ablation [22] or by exposing thin films of fullerenes to high-energy $\mathrm{M}^{+}$-ion beams [59, 60]. Both methods produce mainly ${\mathrm{M} @ \mathrm{C}_{60} \text {, but }}^{\text {a }}$ with low yields. Bulk amounts are obtained so far only for $\mathrm{Li}_{\mathrm{C}} \mathrm{C}_{60}$ [61], which can be stabilized in the form of cationic salts such as $\left[\mathrm{Li}^{+} @ \mathrm{C}_{60}\right] \mathrm{SbCl}_{6}{ }^{-}$[62]. Among the alkali earth metals, Be and Mg are not forming EMFs, whereas $\mathrm{Ca}, \mathrm{Sr}$, and Ba yield monometallofullerenes $\mathrm{M}^{(1)} \mathrm{C}_{2 n}$ in the arc-discharge synthesis with a broad range of carbon cage sizes [63, 64]. Divalent lanthanides ( $\mathrm{Sm}, \mathrm{Eu}, \mathrm{Tm}, \mathrm{Yb}$ ) behave similarly to alkali earth metals in terms of the broad variety of monometallofullerenes they form in the arc-discharge synthesis [65, 66]. For Sm-EMFs, a series of dimetallofullerenes $\mathrm{Sm}_{2} @ \mathrm{C}_{2 n}[67,68]$ and even a trimetallofullerene $\mathrm{Sm}_{3} @ \mathrm{C}_{80}$ has been also characterized [69].

The group IIIB elements Sc, Y, and La, as well as trivalent rare earth elements, are the most versatile metals in the EMF field as they produce a broad range of different types of EMFs, from monometallofullerenes and dimetallofullerenes (also known as classical EMFs) to a variety of clusterfullerenes. In group IVB, formation of EMFs was achieved for $\mathrm{Ti}, \mathrm{Zr}$, and Hf. Laser ablation with these transition metals gives mono-metallofullerenes $\mathrm{M@C}_{2 n}$ $(2 \mathrm{n}=26-46)$, with the most abundant species at $2 \mathrm{n}=28$ and 44 [70]. Unfortunately, bulk amounts of these small-cage monometallofullerenes are not available. Arc-discharge synthesis of Ti-EMFs yields several structures with one and two Ti atoms within the cage,
 bide clusterfullerenes (CCFs), i.e. $\mathrm{Ti}_{2} \mathrm{C}_{2} @ \mathrm{C}_{78}$ [72]. Other CCF synthesized are the recently found $\mathrm{Ti}_{2} \mathrm{C}_{2} @ \mathrm{C}_{82}$ instead of $\mathrm{Ti}_{2} @ \mathrm{C}_{84}$ [71, 73]. Other Ti-EMFs have been observed in mass spectra, however, their molecular structures are not known yet. Titanium has been also encapsulated in EMFs in the form of several types of clusterfullerenes, including aforementioned $\mathrm{Ti}_{2} \mathrm{C}_{2} @ \mathrm{C}_{78}$, mixed-metal NCFs $\mathrm{TiM}_{2}{\mathrm{~N} @ \mathrm{C}_{80}}(\mathrm{M}=\mathrm{Sc}$ and Y ; Ti alone cannot form NCFs) [74], sulfide $\mathrm{Ti}_{2}{\mathrm{~S} @ \mathrm{C}_{78}}^{\text {[75] }}$, and carbide $\mathrm{TiLu}_{2}{\mathrm{C} @ \mathrm{C}_{80}}^{\text {[76] }}$. The information on the arc-discharge synthesis of Zr and Hf-EMFs is rather scarce. Both metals were found to form small amounts of EMFs [77]. In a later work, $\mathrm{Hf}^{( } \mathrm{C}_{84}$ and $\mathrm{Hf}_{2} @ \mathrm{C}_{80}$ were isolated and studied spectroscopically, but their molecular structures were not elucidated [78].

The limited availability of actinides precludes detailed studies of their EMFs. Formation of EMFs with Ac, Th, Pa, U, Np, and Am in the arc-discharge process was reported [17-20] and classified into two groups: $\mathrm{Ac}, \mathrm{U}, \mathrm{Pu}, \mathrm{Np}$, and Am are similar to the trivalent lanthanide analogs, whereas Th and Pa are substantially different. Sufficient amounts of purified actinide-EMFs for spectroscopic characterization were so far only obtained for $\mathrm{U} @ \mathrm{C}_{82}$ and $\mathrm{Th}^{( } \mathrm{C}_{84}$ [18]. In laser ablation studies, uranium produces a series of monometallofullerenes with the largest abundance of ${\mathrm{U} @ \mathrm{C}_{28}}$ and $\mathrm{U}_{2} @ \mathrm{C}_{60}$ [23], whereas Th gives a series of monometallofullerenes with maxima abundances at $\mathrm{Th}^{(1)} \mathrm{C}_{36}$ and $\mathrm{Th} @ \mathrm{C}_{44}$ [22].

These experimental results can be summarized as follows: (1) mass spectrometry provided the crucial evidence that led to the discovery of metallofullerenes in 1985 and has always played a key role in their identification and characterization. (2) Many metals, including

### 2.3. FORMATION OF ENDOHEDRAL METALLOFULLERENES

group IIIB metals, most of the lanthanide series elements, and Zn of the group IIB have been encapsulated into a fullerene cage to form mono-, di-, and trimetallofullerene using the arc-evaporation technique. (3) Some endohedral metallofullerenes such as group IIIB metals, most of the lanthanide series elements, group IIB metals, and some of their isomers have been successfully isolated and purified by high-performance liquid chromatography (HPLC) technique $[18,23,46,52,54,65,66,70]$. (4) The information on the electronic structures and properties of endohedral metallofullerenes has been obtained by various spectroscopic methods such as EPR (Electron Paramagnetic Resonance), UV-VIS-NIR (Ultraviolet, visible and Near-Infrared) and XPS (X-ray Photoelectron Spectroscopy) as well as by electrochemical characterization such as CV (Cyclic Voltammetry) [17, 19, 66, 78]. (5) It is generally accepted that three-electron transfer to the fullerene cage is favorable for $\mathrm{M}=\mathrm{Y}, \mathrm{La}, \mathrm{Ce}, \mathrm{Pr}, \mathrm{Nd}, \mathrm{Gd}$, $\mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho}, \mathrm{Er}$ and Lu whereas two-electron transfer is preferred for $\mathrm{M}=\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}, \mathrm{Sc}$, $\mathrm{Sm}, \mathrm{Eu}, \mathrm{Tm}$ and $\mathrm{Yb}[15,45,49,79]$. (6) Theoretical calculations on the endohedral metallofullerenes have made an important contribution to their structure elucidation by predicting the symmetry of the cage, the position of the metal atom(s) inside the cage, the number of electrons transferred between metal atom(s) and the fullerene cage, etc. [5, 6, 51, 79, 80] (7) Endohedral metallofullerenes play an important role in a number of fields of applied science, including their introduction as acceptor materials for use in photovoltaic devices [81-83]. They are technological relevant in biomedicine, where they are used as contrast agents in magnetic resonance [12] and X-ray imaging [13], as radiotracers and radiopharmaceuticals [14], as well as antitumour [84] and antimicrobial [85] drugs.

### 2.3 Formation of Endohedral Metallofullerenes

Different strategies have been developed for preparing macroscopic amounts of endohedral fullerenes. These include vaporization of graphite, implantation of the atoms through the walls of already existing carbon cages, and chemical routes via opening and closing the fullerene cages (see Figure 2.6). Among these different methodologies, the vaporization of graphite and in particular, the laser ablation and the arc-discharge method are the two
most popular synthesis procedures [10, 11]. In such procedures, carbon needs to be exposed to very high temperatures [10, 11], and the condensation process of the carbon vapor or hydrocarbon fragments plays a crucial role for the self-assembly of the fullerene cages [86]. The arc-discharge method is simple and cost-effective. However, the uncontrolled process that occurs in the arc does not allow the use of this technique to study the formation mechanism of endohedral fullerenes. Nevertheless, it is the most extensively employed method for the synthesis of endohedral fullerenes [16]. On the other hand, the laser ablation method is suited to study the growth mechanism of fullerenes and EMFs [22, 50]. However, the apparatus, including the laser source, is very expensive, and the EMF synthesis rate is very low. The use of this method for the bulk production of EMFs is thus not feasible.

Figure 2.6: Different approaches to synthesize endohedral fullerenes. (i) Encapsulation during the fullerene formation such as in laser ablation or arc-discharge methods. (ii) Encapsulation into already available empty fullerene; typical variants are implantation (through ion beam or high pressure-high temperature treatment) and molecular surgery (encapsulation is achieved in a series of chemical reactions opening and closing the carbon cage). Image taken from ref. [51].

Despite the large amount of investigations carried out since the discovery of the Buckminsterfullerene [22, 50, 87-97], it remains unknown how fullerenes and metallofullerenes are formed in the high temperature plasma of arc-discharge or laser vaporization. Several models have been suggested to explain the formation of fullerenes, among them are the "party line" [87], the "pentagon road" [90], the "fullerene road" [88], the "ring-stacking" [88], and "ring fusion spiral zipper" [91]. All of these models are based on the same concept, i.e. growing up from intermediate structures and additions of small carbon $\mathrm{C}_{2}$ units in a thermodynamic equilibrium [86]. Recently, some important progress in experimental investigations on growth mechanisms has been reported [22,50,93]. Theoretical studies based on quantum chemical

### 2.4. MOLECULAR STRUCTURES OF ENDOHEDRAL METALLOFULLERENES

modeling of reaction pathways have attempted to follow the proposed formation mechanism by identifying their associated transition states and intermediates. We refer the reader to a brief overview of these studies in references [92], [96] and [97].

Usually, the arc-discharge synthesis simultaneously produces many different EMFs structures as well as empty fullerenes, and extended chromatographic procedures, such as HPLC and recycling HPLC, are required to separate EMFs from empty fullerenes and from each other to obtain them in pure forms both in composition and isomerism. The need for chromatographic separation is therefore one of the main bottlenecks on the way to the broader availability of EMFs [16, 98]. To circumvent this problem, improved separation methods have been proposed permitting increased amounts of isolated metallofullerenes, which can now be purified from extracts with complex product distributions [99-101].

### 2.4 Molecular Structures of Endohedral Metallofullerenes

Molecular structure elucidation of endohedral fullerenes is not very straightforward. In addition to the low availability of the structurally and isomerically pure samples, the main structure elucidation tools such as single-crystal X-ray diffraction and nuclear magnetic resonance (NMR) (particularly ${ }^{13} \mathrm{C}$ NMR) have severe difficulties (vide infra). Even more, other studies such as powder diffraction cannot provide sufficient data to unambiguously unravel the complicated spherical arrangement of carbon atoms, and mass spectroscopy data cannot distinguish between interior and exterior species and those that comprise part of the fullerene cage [16, 51, 102]. Single-crystal X-ray diffraction studies of fullerenes are hampered by the rotational disorder of the fullerene molecules in their crystals, which usually precludes direct determination of the carbon cage structures. Furthermore, endohedral species often have several possible positions inside the carbon cage, which makes the disorder problem even more complicated for EMFs [103, 104]. Low sensitivity of ${ }^{13} \mathrm{C}$ NMR spectroscopy and paramagnetism of many EMF molecules are also serious drawbacks in the structure elucidation. Besides, ${ }^{13} \mathrm{C}$ NMR spectroscopy gives only the symmetry of the carbon cage, and the structure can not be confirmed if many isomers share the same symmetry [16, 51].

In single-crystal X-ray diffraction studies, two strategies have been developed to circumvent the rotational disorder problem. These are, on the one hand, the use of cocrystallizing agents such as Ni- or Co-octaethylporphyrines [105], and, on the other, the exohedral chemical derivatization of the EMF, usually via cycloadditions [106]. Both approaches hinder rotation of EMF molecules in their crystals and often (but not always) reduce disorder in the positions of endohedral species, thus enabling determination of atomic coordinates. With the use of these two approaches, the molecular structures of dozens of EMFs were elucidated by single-crystal X-ray diffraction $[45,107]$.

In the field of NMR spectroscopic studies of EMFs, structural analysis became more accessible in the last decade. ${ }^{13} \mathrm{C}$ NMR studies of paramagnetic EMFs, whose paramagnetism is caused by the odd number of electrons transferred to the carbon cage, have been carried out on their ionic forms obtained by electrolysis. Actually, NMR studies have been successfully performed on paramagnetic EMFs with endohedral lanthanide atoms [108-110]. For example, the $\mathrm{C}_{2 \mathrm{v}}$ symmetry of the carbon cage in paramagnetic $\mathrm{La} \mathrm{C}_{82}$, was determined by the study of its diamagnetic anion [108, 109]. In addition to the carbon cage symmetry, NMR studies also showed that the $\mathrm{Sc}_{2} @ \mathrm{C}_{84}$ firstly assigned as dimetallofullerene, in fact was $\mathrm{Sc}_{2} \mathrm{C}_{2} @ \mathrm{C}_{82}$ a metal-carbide endohedral fullerene [111, 112].

Other spectroscopic techniques, like UV-VIS-NIR, IR or Raman, can also help in the structure elucidation of endohedral fullerenes. The UV-VIS-NIR absorption spectra are usually dominated by the $\pi \rightarrow \pi^{*}$ excitations of the carbon cage and are highly structure sensitive. Due to this, the absorption spectra of EMFs with the same carbon cage isomer in the same formal charge state are very similar [15]. In fact, the UV-VIS-NIR absorption spectra of EMFs can be used as an indirect technique for structure elucidation of newly isolated EMFs by comparison to the spectra of homologues EMFs (but with different metal atoms) whose structures are already described and elucidated in the literature [15, 16]. Vibrational IR and Raman spectroscopies exhibit also similar sensitivity to the molecular structure of fullerenes [113]. However, to determine EMF structures based on vibrational spectra, it is usually necessary to compare with theoretical modeled spectra of several possible structural isomers [16, 114, 115]. Clearly, the success of such studies strongly depends not only on the availability

### 2.5. PROPERTIES AND POTENTIAL APPLICATIONS

and quality of the EMF samples, but also on the reliability of theoretical methods and the range of considered isomers [16, 102, 114].

### 2.5 Properties and Potential Applications

Endohedral metallofullerenes have been attracting wide interest all over the world over the past two decades [15, 16, 46]. To date, a wealth of EMFs has been synthesized and isolated. These novel materials exhibit unique properties resulting from the electron transfer of the encapsulated species (metal ions or clusters) to the carbon cage. Therefore, EMFs not only inherit the properties of the carbon cage and the encapsulated species but also exhibit intriguing properties which are derived from the intramolecular interaction between the carbon cage and the encapsulated species, covering their electrochemical, photophysical, magnetic and electronic transport properties $[15,116,117]$.

Since their discovery, low production yield and tedious HPLC separation have hindered the research on EMFs. Such experimental difficulties are sometimes responsible for the erroneous assignment of metal-carbide clusterfullerenes as classical EMFs, as in the case of $\mathrm{Sc}_{2} \mathrm{C}_{2} @ \mathrm{C}_{82}$ mentioned before. Shinohara et al. demonstrated that the $\mathrm{TiCl}_{4}$ Lewis acid can be employed to effectively and quickly separate and purify diverse classical and carbide EMFs from empty fullerenes [99]. The EMFs featuring a first oxidation potential ( ${ }^{o x} \mathrm{E}_{1}$ ) lower than 0.5 to 0.6 V vs. $\mathrm{Fc} / \mathrm{Fc}^{+}$(ferroceneferrocenium electrode) (this threshold was adjusted to $0.62-0.72 \mathrm{~V}$ vs. $\mathrm{Fc} / \mathrm{Fc}^{+}$in a later report [100]) might react with $\mathrm{TiCl}_{4}$ to afford stable complexes and become highly purified. All the ${ }^{o x} \mathrm{E}_{1}$ values for the metal-carbide clusterfullerenes reported so far meet this requirement and can be separated efficiently. These methods may replace the conventional HPLC technique and promises a brighter future for the high-efficiency isolation of EMFs [99].

As already mentioned, the special electronic structure and the internal metal atoms in EMFs result in various magnetic properties, such as paramagnetism, ferromagnetism and antiferromagnetism. These properties have promising applications in quantum information processing, memory devices, medical imaging, single-molecule magnet (SMM), and spintronics
$[46,117] . \mathrm{La} @ \mathrm{C}_{82}$ was the first paramagnetic EMF studied by electron spin resonance (ESR) spectroscopy. Subsequently, other EMFs have been investigated for their magnetic properties [118, 119]. For instance, the electron spin modulation based in paramagnetic EMFs, such as $\mathrm{Sc}_{\mathrm{c}} @ \mathrm{C}_{82}\left(\mathrm{C}_{2 \mathrm{v}}\right)$ and $\mathrm{Y}_{2} @ \mathrm{C}_{79} \mathrm{~N}$, have been realized by changing temperatures and exohedral modifications, and this promises the prospect of EMF applications in quantum information processing and single-molecule magnets [120-122]. Likewise, other systems such as Dy-based clusterfullerenes, e.g., $\mathrm{DySc}_{2} \mathrm{~N}^{( } \mathrm{C}_{80}$ and $\mathrm{Dy}_{2} \mathrm{ScN}^{\mathrm{N}} \mathrm{C}_{80}$, were found to show single molecular magnetic (SMM) behavior, which is very promising for spintronic applications [123, 124].

Effective isolation of endohedral metals from the surrounding environment by the carbon cage makes EMFs promising for different types of biomedical applications. Particularly, Gd-EMFs have received considerable attention as a new type of contrast agent in magnetic resonance imaging (MRI) [125]. Nowadays, the most commonly used commercially available MRI contrast agents are gadolinium chelate complexes such as Gd-DTPA (DTPA: diethylenetriamino-pentaacetic acid), which uses the $\mathrm{Gd}^{3+}$ ion to enhance the relaxation rate of water protons [126]. However, unavoidable release of toxic $\mathrm{Gd}^{3+}$ in such complexes, although very small, may lead to unpredictable side effects. To overcome this health risk Gd-EMFs have been suggested as alternatives. Experimental studies conducted with some Gd-EMFs (the most studied are $\mathrm{Gd}_{2} \mathrm{C}_{2} @ \mathrm{C}_{84}$ and $\mathrm{Gd}_{2} \mathrm{C}_{2} @ \mathrm{C}_{92}$ ) showed that they induce a much higher relaxation rate of water protons than Gd-DTPA and similar complexes [127, 128]. To date, various water-soluble derivatives of gadofullerenes have been synthesized and investigated for their imaging properties [129, 130]. Gd-EMFs can be used not only to enhance MRI contrast but also as antitumor drugs. Another promising route for applications of EMFs in medicine is their use as radioactive-tracers or radioactive-pharmaceuticals [14, 131].

## Chapter 3

## Theoretical Methodology

### 3.1 Topological Methodology

The discovery of the Buckminsterfullerene offered a new opportunity for the collaboration between mathematicians and chemists, since fullerenes are examples of discrete mathematical structures where graph theory, combinatorics and symmetry may generate qualitative chemical understanding [132]. One of the main issues tackled with mathematics is the listing (generate and enumerate) of all fullerene isomers for a given number of carbon atoms. The first approach in this direction was the spiral algorithm in 1991 [29, 33]. Unfortunately, this method misses some isomers when $n \geq 380$ [133]. To overcome this limitation, different approaches were developed based on the general idea of transformation and vertex insertion methods, such as the Goldberg-Coxeter (GC) construction [134], and the Stone-Wales (SW), Endo-Kroto (EK) [135] or Leapfrog transformations [29], making possible the generation of equal or larger sized fullerene structures starting from an existing one.

These approaches are found in the two most common programs to generate fullerenes, namely Fullerene [136] and CaGe (which also includes fullgen and buckygen) [137]. Fullerene employs the spiral algorithm and a modified version [138] of it to list fullerene isomers, but for those isomers that can not be constructed in this way it uses generalized versions of the GC construction and SW, EK and Leapfrog transformations on smaller fullerenes. On the
other hand, CaGe employs a very particular implementation [139-141], based on the general idea behind transformation and vertex insertion procedures, which results in a slightly faster generation of fullerene isomers without further information (symmetry point group). For practical applications it is important to note that the isomer enumeration differs in these two programs. Despite the three dimensional nature of fullerenes, the mentioned algorithms work with a 2D-representation known as fullerene dual graph, because it turns out to be more convenient for implementing on a computer. Since the related theory behind this and other concepts could be the subject of an entire thesis in itself, only the fundamental ideas will be treated in a brief and general way in this chapter.

### 3.1.1 Fullerene Duals

The fullerenes by themselves are mathematically well defined objects, being pseudospherical polyhedral shells of carbon atoms in which each atom (vertex $[v]$ ) is linked by a bond (edge $[e]$ ) to the three nearest neighbors, and all rings (faces $[f]$ ) are either pentagonal or hexagonal. One useful property of polyhedra, which will find application in this chapter, is that all polyhedra have duals. In a fullerene's dual, faces and vertices have switched roles, i.e., the vertices of a polyhedron correspond to the faces of its dual, and vice versa (see Figure 3.1). The dual operation is its own inverse, and preserves the point group symmetry of the polyhedron. Effectively, this operation corresponds to interchanging $v$ and $f$ in Euler's theorem while leaving $e$ unchanged [29].

Figure 3.1: The dodecahedron (solid lines) and its dual, the icosahedron (dotted lines).

### 3.1. TOPOLOGICAL METHODOLOGY

Duals are interesting because it is often easier to construct a fullerene by first constructing its dual. In fact, this trick forms the basis of several programs for the generation of fullerene isomers. The duals of fullerenes are deltahedra, which are polyhedra made up exclusively of triangular faces [29]. Once the dual is known, the fullerene can easily be reconstructed, because each set of three mutually adjacent vertices in the dual encloses a unique triangular face that maps uniquely into a vertex of the corresponding fullerene polyhedra. From this unique mapping between triangular faces in the dual and vertices in the fullerene, it immediately follows that two vertices in a fullerene will be adjacent if and only if their corresponding triangular faces in the dual share a side. This allows us to obtain a list of adjacent vertices in the fullerene from a list of adjacent vertices in its dual, which is equivalent to perform the reconstruction [29].

### 3.1.2 Fullerene Graphs

Another useful property of polyhedra is that they can be flattened onto a plane in such a way that the edges intersect only at the vertices. This is called a graph or, in the case of fullerenes, a fullerene graph. Mathematically, a graph $G=(\mathcal{V}, \mathcal{E})$, is a set of vertices $(\mathcal{V})$ connected by edges $(\mathcal{E})$. The drawing of a graph in two- or three-dimensional space without edge crossings is known as a 2D or 3D embedding (see Figure 3.2) [136]. In two dimensions this is also called a planar embedding.

In a graph, the number of neighbors to a vertex $v$, that is, the number of edges incident to $v$, is denominated as its valency or degree. A vertex with valency $k$ is said to be $k$-valent or $k$-connected. In addition, a graph is called $k$-regular if every vertex is $k$-valent. Thus, a fullerene graph is a 3 -connected 3 -regular planar graph that represents and describes without ambiguity a three-dimensional polyhedra $[29,136]$.

The dual graph, $G^{*}$, of a planar 3-connected graph, $G$, is a graph that has a vertex for each face of $G$. That is, dual operation transforms a graph by replacing every one of its faces with vertex; a pair of such vertices will be joined by an edge only if they originate from adjacent faces. The resulting graph, $G^{*}$, is just another, equivalent, representation of $G$ since
$\left(G^{*}\right)^{*}=G$, that is, the dual operation is an involution [136, 142].

Figure 3.2: Planar embeddings of fullerene graph (black lines represent edges and red points vertices) and its dual (blue lines represent edges and pink dots vertices), along with a 3D embedding of the dual for the $\mathrm{C}_{20}$ (Image partially taken from ref. [136])

### 3.1.3 Generation of Fullerene Graphs

### 3.1.3.1 The Spiral Conjecture and Algorithm

One of the first methods for the generation of fullerene graphs was the spiral algorithm by Manolopoulos et al. [33] The basic idea behind this algorithm is that one can unwind the surface of a graph "like an orange peel". The spiral algorithm is based on the spiral conjecture, which states that: "The surface of a fullerene polyhedra may be unwound in a continuous spiral strip of edge-sharing pentagons and hexagons such that each new face in the spiral after the second shares an edge with both (a) its immediate predecessor in the spiral and (b) the first face in the preceding spiral that still has an open edge". This conjecture can be stated equivalently for a fullerene's dual [29]. More practically, this algorithm simply generates all possible spiral sequences (each one of them with a length of $n / 2+2$ ) of pentagons and hexagons for a given $\mathrm{C}_{n}[29,136]$.

As the spiral conjecture is worked out, the first face in the spiral sequence can be any of the $n / 2+2$ faces of the $\mathrm{C}_{n}$ fullerene. Thus, every $\mathrm{C}_{n}$ fullerene has a total of $6 n$ possible spiral starts, but sometimes it happens that the entire graph surface cannot be unwound (the spiral sequence can not be completed) subject to the constraints of the conjecture, in which case the spiral is discarded. Hence, $6 n$ is generally an upper bound for the number of spiral

### 3.1. TOPOLOGICAL METHODOLOGY

that can be found for a $\mathrm{C}_{n}$ fullerene [29, 136]. Figure 3.3 shows $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ and $\mathrm{C}_{70}\left(\mathrm{D}_{5 \mathrm{~h}}\right)$ being successfully unwound into the corresponding spirals: 56666656565656566565656565666665 and 5666665656565656666666666656565656565, respectively, where the 5's and 6's stand for pentagonal and hexagonal faces. It is important to note that the last pentagonal face of each spiral (red 5 in the above spirals) corresponds to the outer pentagon, which encloses all other faces (red pentagon in Figure 3.3).

Figure 3.3: Unwinding $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ and $\mathrm{C}_{70}\left(\mathrm{D}_{5 \mathrm{~h}}\right)$ into face spirals (Image partially taken from ref. [29])

All possible $\mathrm{C}_{n}$ fullerene graphs can be generated by considering the $(n / 2+2)!/ 12!(n / 2-$ 10)! ways in which the pentagons and hexagons positions along the spiral can be arranged. Once all of these spiral sequences have been generated for a given $\mathrm{C}_{n}$ fullerene, the next step is to check whether they wind up to a fullerene or not. The task, however, is not complete, since a fullerene can be unwound into up to $6 n$ spirals, and hence each fullerene will be generated many times. A simple way to solve this problem is checking the uniqueness of the given fullerene. As an example, take the following, three distinct spirals for the $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$

$$
\begin{equation*}
56666656565656566565656565666665 \tag{3.1}
\end{equation*}
$$

$$
\begin{equation*}
65656566656656656566566565656566 \tag{3.2}
\end{equation*}
$$

$$
\begin{equation*}
66565656566566565665665666565656 \tag{3.3}
\end{equation*}
$$

These three spirals wind up to give the same polyhedron, and hence all three spirals are
equivalent. However, they can also be seen as 32-digit integer numbers, with magnitudes $(3.1)<(3.2)<(3.3)$. Therefore, the smallest sequence is defined as the canonical spiral representation of the fullerene graph. In this example, the canonical spiral of icosahedral $\mathrm{C}_{60}$ is given by Eq. (3.1) [29, 136].

As pointed out previously, the spiral algorithm fails in some cases, since not all fullerenes can be unwound into a spiral sequence. However, an extended version of this algorithm accounts for these failures [29, 33, 138]. Nonetheless, it is extremely inefficient to generate all $\mathrm{C}_{n}$ isomers. Therefore, more efficient graph generation methodologies, like transforming an existing fullerene graph into a new one by local or partial transformations (that leave all but a certain region of the graph unchanged) and global or total transformations [132, 136, 142], have been developed.

### 3.1.3.2 The Goldberg-Coxeter Construction

The most abundant fullerene isomer, the Buckminsterfullerene $\left(\mathrm{C}_{60}\right)$ has an icosahedral symmetry. However, fullerenes can possess other symmetries. More information about it can be found directly in the Atlas of Fullerenes [29], and Topology of fullerenes [136], among other references [143].

The common feature of all icosahedral fullerenes is their geometrical shape. Since all the vertices of the icosahedron are equivalent, they lie at the same distance from its center and may be placed on the surface of a sphere. The edges can also be distorted to lie on this sphere, as sections of great circles between the vertices. The resulting faces are spherical triangles, and the hole object is an icosahedral triangulation of the sphere [29, 142]. The Goldberg-Coxeter method was developed using this idea to produce larger spherical deltahedra of icosahedral symmetry beginning from a smaller ones [134, 142, 144, 145]. In fact, this method is a generalization of the approaches published independently by Goldberg in 1937 [144] and Caspar and Klug in 1962 [146], and then revisited and popularized by Coxeter [147].

The GC construction takes as basic idea the way in which the icosahedron (the dual of the $\mathrm{C}_{20}$ fullerene) can be assembled from the unfolded representation shown in Figure 3.4. Generalizing this idea, it was proposed that all icosahedral fullerenes can be obtained by

### 3.1. TOPOLOGICAL METHODOLOGY

mapping an unfolded icosahedron (like the one depicted in Figure 3.4) onto a hexagonal (or triangular) lattice scaled and orientated in such a way that the vertices of the unfolded icosahedron fall on the centers of some hexagons of the grid [29, 134, 136, 142].

Figure 3.4: Unfolding the icosahedron, the dual of the fullerene polyhedra $\mathrm{C}_{20}$.

In more detail, a dual graph is obtained by superposing a planar net of the icosahedron (20 equilateral triangular faces) on a 2D hexagonal lattice (see Figure 3.5) by means of a coordinate system $(k, l)$, where $k$ and $l$ are integers describing the scale and orientation of the equilateral triangles in the lattice. The new polyhedron obtained in this way has exactly 12 pentagonal faces (vertices of the triangles are centers of the 12 pentagons) and many hexagonal faces, corresponding to a fullerene with $n=20\left(k^{2}+k l+l^{2}\right)$ vertices [134, 145]. Figure 3.5 shows the construction of a planar net with $(k, l)=(1,1)$ (the buckminsterfullerene $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ ) in the hexagonal lattice basis $\mathbf{e}_{1}$ and $\mathbf{e}_{2}$. Denoting one of the icosahedral vertices as O , the construction is as follows: From the vertex O move along $k$ edges, then change direction by $60^{\circ}$ and move along $l$ edges to give a second vertex. Two more repetitions of this maneuver recover the starting point having marked out a large equilateral triangle. Then, gluing 19 copies of this equilateral triangle in a coherent way forms an unfolded icosahedron as the one shown in Figure 3.5. Precisely 20 such $(k, l)$-triangles produce a $(k, l)$-icosahedral fullerene, by assembling the net along with the hexagonal lattice etched onto its faces, as Figure 3.6 shows.

Figure 3.5: The Goldberg-Coxeter method for fullerene graphs with icosahedral symmetry. A superposition of an icosahedral net on a hexagonal tessellation determines the positions of hexagonal and pentagonal faces in a fullerene. The example shows the construction for a (1,1)-icosahedral fullerene, the $\mathrm{C}_{60}$.

### 3.1. TOPOLOGICAL METHODOLOGY

The fullerenes given by the equation $n=20\left(k^{2}+k l+l^{2}\right)$ with $k>0, l \geq 0, k \geq l$ (each distinct $(k, l)$ pair gives a distinct isomer) are polyhedra with icosahedral symmetry. Figure 3.6-c ilustrates three icosahedral fullerenes by showing a single face of the icosahedron upon which each structure is based. The GC method can be generalized to give fullerenes of other symmetries, but as the symmetry decreases the method becomes more complicated. More information about the GC method can be found in references [29] and [136].

### 3.1.3.3 Stone-Wales and Endo-Kroto Transformations

A fullerene can be transformed locally by replacing a patch of its structure by either a different patch or the same in a different orientation, in order to obtain a new fullerene graph [136, 148]. A patch is a set of faces (pentagonal or hexagonal) that is bounded by a simple cycle, that is, a cycle that traverses no vertex or edges twice [135]. Depending on the patch repleacement, these operations are divided into isomerization and growth operations. Isomerizations replace patches by others of equal size, whereas growth operations enlarge or reduce these patches. The most prominent example of isomerization operations is the StoneWales transformation,[149] while for growth operations it is the Endo-Kroto transformation [150]. Extendended reformulations [139-141] of these methods are the basis of the currently fastest fullerene graph generator implemented in the CaGe program. However, as already mentioned, here only these two operations will be addressed.

### 3.1.3.3.1 Stone-Wales Transformations

For the Stone-Wales (SW) transformation it is first necessary to find a place on the surface of the fullerene polyhedron where two hexagons and two pentagons meet in a patch (see Figure 3.7). If such a patch exist, the central bond can be twisted, producing a "rotated" patch within the same perimeter of 12 atoms and 12 bonds. The product is still a fullerene but different from the starting isomer [136, 142, 151].

Figure 3.7: The Stone-Wales transformation.

This transformation has been suggested as a possibility for the mechanism of rearrangement in high temperature enviroments [152]. The SW transformation is believed to be one of the main mechanisms by which fullerene cages equilibrate during formation to form the most stable isomer [92, 153]. However, as a general scheme for generating new fullerene isomers from an initial one, the SW transformation is incomplete, e.g. starting from $\mathrm{C}_{60}\left(\mathrm{I}_{\mathrm{h}}\right)$ only a portion (1709 isomers) of the 1812 possible $\mathrm{C}_{60}$ fullerene isomers are accessible by consecutive SW transformations [151, 154].

### 3.1.3.3.2 Endo-Kroto Transformations

The Endo-Kroto (EK) transformation involves a patch with two pentagons linked to opposite edges of a central hexagon. To this patch are added two vertices ( $\mathrm{C}_{2}$ insertion) within its 12-vertex boundary, as shown in Figure 3.8. This transformation results in a bigger fullerene, i.e. a fullerene with $n+2$ vertices [136, 140, 150].

Figure 3.8: A hypothetical mechanism for expansion of a fullerene by a two carbon atom insertion.

The EK $\mathrm{C}_{2}$ insertion has also been proposed as a possible reaction pathway for fullerene growth [150, 155]. Also, patch replacements (SW and EK transformations) have been useful from a graph theoretical point of view, since these have been used as a basis for subsequent

### 3.1. TOPOLOGICAL METHODOLOGY

reformulations of methods to generate fullerene isomers [139-141]. However, since the pentagons can be arbitrarily far away from each other, no finite set of transformations are usaully sufficient to generate all possible fullerene graphs [142, 151].

### 3.1.3.4 The Leapfrog Transformation

The Leapfrog operation on a fullerene graph $G, L(G)$, is usually used for the construction of bigger IPR fullerenes [142]. To understand how this operation works, let us consider the dodecahedron $\mathrm{C}_{20}$. If this structure is capped (the omnicapping operation adds a vertex in the center of each face of a planar graph, and connects the new vertex with each boundary vertex of the corresponding face [156]) over every face it becomes a deltahedron with 12 five-valent and 20 six-valent vertices. If the deltahedron is then converted to its dual, the 32 vertices become face centers and the 60 triangular faces become 60 vertices of a truncated icosahedron (i.e. of icosahedral $\mathrm{C}_{60}$ ), as shown in Figure 3.9 [29, 156].

Figure 3.9: Leapfrogging a dodecahedron: A dodecahedron is converted to a 32 -vertex deltahedron by capping, then to a truncated icosahedron by taking the dual.

By capping and dualizing the original fullerene, a new fullerene with three times as many vertices has been created. The procedure is nicknamed the leapfrog transformation because it jumps from one fullerene to another over the intervening deltahedron. This procedure can be used for any fullerene whether it is icosahedral or not [29].

### 3.2 Quantum Chemical Methodology

### 3.2.1 The Schrödinger Equation

The ultimate goal of most quantum chemical approaches is to obtain insight into a molecular system by solving the Schrödinger equation [157-161]. In order to simplify the problem, the electronic and nuclear wavevunctions are separated by the Born-Oppenheimer approximation [162, 163]. The resulting electronic Schrödinger equation is cast in the form:

$$
\begin{equation*}
\hat{H} \Psi(\mathbf{r} ; \mathbf{R})=E \Psi(\mathbf{r} ; \mathbf{R}) \tag{3.4}
\end{equation*}
$$

Here $\Psi$ is the electronic wavefunction - a function that depends explicitly on the electronic coordinates $\mathbf{r}$ and parametrically on the nuclear coordinates $\mathbf{R}$. From now on we will omit the parametric dependence on the nuclear coordinates in order to avoid cluttering of the notation. Thus, for an isolated molecular system, the Hamiltonian in Eq. (3.4) describing the interaction of electrons and nuclei becomes:

$$
\begin{equation*}
\hat{H}=-\frac{1}{2} \sum_{i}^{N} \nabla_{i}^{2}-\sum_{i}^{N} \sum_{A}^{M} \frac{Z_{A}}{\left|\mathbf{r}_{i}-\mathbf{A}\right|}+\sum_{i}^{N} \sum_{j>i}^{N} \frac{1}{\left|\mathbf{r}_{i}-\mathbf{r}_{j}\right|} \tag{3.5}
\end{equation*}
$$

In Eq. (3.5), as throughout this thesis, atomic units are used. The position vectors $\mathbf{r}$ and $\mathbf{A}$ denote the spatial coordinates of the electrons and nuclei, respectively. The atomic mass of nucleus $A$ is $M_{A}$ and it's charge $\mathrm{Z}_{A}$. A term-by-term interpretation of Eq. (3.5) reveals that the first term correspond to the kinetic energy of the electrons. The latter two terms denote the potential part of the Hamiltonian in terms of electrostatic particle-particle interactions. These are the electrostatic attraction between the $N$ electrons and the $M$ nuclei and the electrostatic repulsion between the $N(N-1) / 2$ electron pairs [164].

Apart from a small subset of physical systems, mainly one-electron systems, the electronic Schrödinger equation cannot be solved analytically. Thus, only approximate solutions are available for most chemical systems of interest. Several methods have been developed for this

### 3.2. QUANTUM CHEMICAL METHODOLOGY

purpose [165, 166], the most relevant being the ones based on the Rayleigh-Ritz variational method [167, 168]. The variational principle in quantum mechanics states that any approximate wavefunction will always have an energy expectation value that is above that of the ground state energy [169, 170]

$$
\begin{equation*}
E_{e}\left[\Psi_{t}\right] \geq E_{e}\left[\Psi_{0}\right] \tag{3.6}
\end{equation*}
$$

where $\Psi_{t}$ and $\Psi_{0}$ denote the trial and ground state wavefunctions, respectively. In other words, the energy expectation value of any appropriate trial wavefunction will provide an upper bound to the exact ground state energy. The variational method allows to approximate a solution to the Schrödinger equation for many-electron systems, nevertheless the task is rather complicated. For an $N$ electron system, $\Psi$ depends on $3 N$ spatial coordinates, thus, even for very simple molecules the number of variables becomes large.

### 3.2.2 Density Functional Theory

Actually, the first attempts to use the electron density, $\rho(\mathbf{r})$, rather than the wavefunction, $\Psi(\mathbf{x})$, for obtaining information about atomic and molecular systems are almost as old as quantum mechanics itself and dates back to the early works of Thomas [171] and Fermi [172] in 1927. Further work by Dirac [173] as well as Wigner and Seitz [174, 175] improved the model by introducing a local expression for the exchange potential. Several years later, Slater introduced the idea of approximating the Fock exchange operator in the Hartree-Fock method by an average local potential based on the free-electron gas model [176]. The result was an exchange potential expressed solely in terms of $\rho(\mathbf{r})$. To improve the quality of this approximation an adjustable, semiempirical parameter $\alpha$ was introduced which led to the $X_{\alpha}$ methodology of Slater and Johnson [177]. The main advantage of such methodologies arises from the fact that the electronic density $\rho(\mathbf{r})$ depends only on 3 instead of $3 N$ spatial variables. The electron density can be expressed as measurable observable only dependent from spatial coordinates:

$$
\begin{equation*}
\rho(\mathbf{r})=N \int d \mathbf{r}_{2} \ldots \int d \mathbf{r}_{\mathbf{N}} \Psi^{*}\left(\mathbf{r}, \mathbf{r}_{2}, \ldots, \mathbf{r}_{N}\right) \Psi\left(\mathbf{r}, \mathbf{r}_{2}, \ldots, \mathbf{r}_{N}\right) \tag{3.7}
\end{equation*}
$$

Strictly speaking $\rho(\mathbf{r})$ is a one-particle probability density, but calling it the electron density is common practice. It should be noted that $\rho(\mathbf{r}) d \mathbf{r}$ represents the number of electrons in a volume element $d \mathbf{r}$. Thus, Eq. (3.7) represents the probability of finding an electron at position $\mathbf{r}$ while the other $N-1$ electrons are at arbitrary positions. Clearly, $\rho(\mathbf{r})$ is a nonnegative function of only the three spatial variables which vanishes at infinity and integrates to the total number of electrons [164]:

$$
\begin{align*}
& \rho(\mathbf{r} \rightarrow \infty)=0 \\
& \int \rho(\mathbf{r}) d \mathbf{r}=N \tag{3.8}
\end{align*}
$$

A rigorous mathematical foundation for an ab initio theory based solely on $\rho(\mathbf{r})$ was first given by Hohenberg and Kohn in 1964, starting what we know today as Density Functional Theory [178]. The Hohenberg and Kohn formulation is based on the following two theorems:

First Hohenberg-Kohn theorem The external potential $v(\boldsymbol{r})$ is a unique functional of the electron density $\rho(\boldsymbol{r})$, apart from a trivial additive constant.

To proof the first Hohenberg-Kohn theorem we assume that there exist two external potentials $v(\mathbf{r})$ and $v^{\prime}(\mathbf{r})$ differing by more than a constant but which both give rise to the same electron density $\rho(\mathbf{r})$. These two potentials are part of two Hamilton operators which only differ in the external potential, $\hat{H}=\hat{T}+\hat{V}_{e e}+v(\mathbf{r})$ and $\hat{H}^{\prime}=\hat{T}+\hat{V}_{e e}+v^{\prime}(\mathbf{r})$. Obviously, the two Hamilton operators $\hat{H}$ and $\hat{H}^{\prime}$ yield two different ground state wavefunctions, $\Psi(\mathbf{r})$ and $\Psi^{\prime}(\mathbf{r})$, and corresponding ground state energies, $\mathrm{E}_{0}$ and $\mathrm{E}_{0}^{\prime}$, respectively. If ground state degeneracy is excluded, then $\mathrm{E}_{0} \neq \mathrm{E}_{0}^{\prime}$ holds. Therefore $\Psi(\mathbf{r})$ and $\Psi^{\prime}(\mathbf{r})$ are different, and we can use $\Psi^{\prime}(\mathbf{r})$ as trial wavefunction for $\hat{H}$ [179]. By virtue of the variational principle (written in Dirac's notation [180]) we obtain:

$$
\begin{equation*}
E_{0}=\langle\Psi| \hat{H}|\Psi\rangle<\left\langle\Psi^{\prime}\right| \hat{H}\left|\Psi^{\prime}\right\rangle=\left\langle\Psi^{\prime}\right| \hat{H}^{\prime}+v-v^{\prime}\left|\Psi^{\prime}\right\rangle=\left\langle\Psi^{\prime}\right| \hat{H}^{\prime}\left|\Psi^{\prime}\right\rangle+\left\langle\Psi^{\prime}\right| v-v^{\prime}\left|\Psi^{\prime}\right\rangle \tag{3.9}
\end{equation*}
$$

### 3.2. QUANTUM CHEMICAL METHODOLOGY

Similarly, taking $\Psi(\mathbf{r})$ as the trial wavefunction for $\hat{H}^{\prime}$ yields:

$$
\begin{equation*}
E_{0}^{\prime}=\left\langle\Psi^{\prime}\right| \hat{H}^{\prime}\left|\Psi^{\prime}\right\rangle<\langle\Psi| \hat{H}^{\prime}|\Psi\rangle=\langle\Psi| \hat{H}+v^{\prime}-v|\Psi\rangle=\langle\Psi| \hat{H}|\Psi\rangle+\langle\Psi| v^{\prime}-v|\Psi\rangle \tag{3.10}
\end{equation*}
$$

Eq. (3.9) and (3.10) can be rewritten as:

$$
\begin{equation*}
E_{0}<E_{0}^{\prime}+\int\left[v(\mathbf{r})-v^{\prime}(\mathbf{r})\right] \rho(\mathbf{r}) d \mathbf{r} \tag{3.11}
\end{equation*}
$$

and

$$
\begin{equation*}
E_{0}^{\prime}<E_{0}+\int\left[v^{\prime}(\mathbf{r})-v(\mathbf{r})\right] \rho(\mathbf{r}) d \mathbf{r} \tag{3.12}
\end{equation*}
$$

Adding Eq. (3.11) and (3.12) we obtain,

$$
\begin{equation*}
E_{0}+E_{0}^{\prime}<E_{0}^{\prime}+E_{0} \tag{3.13}
\end{equation*}
$$

which represents a contradiction and, therefore, provides by reductio ad absurdum the proof that there cannot be two different external potentials that yield the same ground state electron density. In other words, the ground state density uniquely defines the external potential of a non-degenerated quantum mechanical system. Therefore, the following mapping can be defined based on the first Hohenberg-Kohn theorem:

$$
\begin{equation*}
\rho(\mathbf{r}) \mapsto N, v(\mathbf{r}) \mapsto \hat{H} \mapsto \Psi[\rho(\mathbf{r})] \mapsto E[\rho(\mathbf{r})] . \tag{3.14}
\end{equation*}
$$

The consequence of the one-to-one correspondence between the electronic density $\rho(\mathbf{r})$ and the external potential $v(\mathbf{r})$ is that the energy becomes a functional of the density. Due to the fact that the wavefunction is a functional of the ground state density, the expectation value $O$ of any operator $\hat{O}$ is also a unique functional of this density:

$$
\begin{equation*}
\langle\hat{O}\rangle=\langle\Psi[\rho(\mathbf{r})]| \hat{O} \mid \Psi[\rho(\mathbf{r})]=O[\rho(\mathbf{r})] \tag{3.15}
\end{equation*}
$$

Hence all ground state electronic properties are determined by the non-degenerated ground
state density [178]. Among these observables is the ground state energy, the expectation value of the Hamilton operator, which is of great importance. Note that the above proof only shows the existence of $\Psi[\rho]$ and $E[\rho]$. It does not provide any insight into the functional dependencies.

The ground state wavefunction and the corresponding energy related to a potential $v(\mathbf{r})$, can be expressed as a functional of $\rho(\mathbf{r})$ :

$$
\begin{equation*}
E[\rho(\mathbf{r})]=\langle\Psi[\rho(\mathbf{r})]| \hat{H}|\Psi[\rho(\mathbf{r})]\rangle=\int v(\mathbf{r}) \rho(\mathbf{r}) d \mathbf{r}+\langle\Psi[\rho(\mathbf{r})]| \hat{T}+\hat{V}_{e e}|\Psi[\rho(\mathbf{r})]\rangle \tag{3.16}
\end{equation*}
$$

To obtain a more convenient handling of Eq. (3.16), the universal Hohenberg-Kohn functional $F[\rho(\mathbf{r})]$ and subsequently, the energy functional $E[\rho(\mathbf{r})]$ are defined [178]:

$$
\begin{align*}
& F[\rho(\mathbf{r})]=\langle\Psi[\rho(\mathbf{r})]| \hat{T}|\Psi[\rho(\mathbf{r})]\rangle+\langle\Psi[\rho(\mathbf{r})]| \hat{V}_{e e}|\Psi[\rho(\mathbf{r})]\rangle \\
& E[\rho(\mathbf{r})]=F[\rho(\mathbf{r})]+\int v(\mathbf{r}) \rho(\mathbf{r}) d \mathbf{r} \tag{3.17}
\end{align*}
$$

The name universal arises from the fact that $F[\rho(\mathbf{r})]$ does not depend on the external potential $v(\mathbf{r})$ and, therefore, is a universal functional for all systems, i.e. model systems, atoms, molecules and solids [181].

Although the Hohenberg-Kohn theorem establishes the fact that the wavefunction and energy are functionals of the ground state electronic density, it does not, however, prescribe the explicit dependencies of $\Psi(\mathbf{r})$ and E from $\rho(\mathbf{r})$. Nevertheless, the variational energy principle can be used to obtain the ground state density as proven by the following theorem:

Second Hohenberg-Kohn theorem: The ground state density $\rho(\mathbf{r})$ can be determined from the ground state energy functional $E[\rho(\mathbf{r})]$ via the variational energy principle by variation of the density only.

The ground state energy $E_{0}$ which is a functional of the ground state density is given by:

$$
\begin{equation*}
E_{0}\left[\rho_{0}(\mathbf{r})\right]=\left\langle\Psi_{0}\left[\rho_{0}(\mathbf{r})\right]\right| \hat{H}\left|\Psi_{0}\left[\rho_{0}(\mathbf{r})\right]\right\rangle \tag{3.18}
\end{equation*}
$$

### 3.2. QUANTUM CHEMICAL METHODOLOGY

For a trial density $\rho_{t}(\mathbf{r})$, such that $\int \rho_{t}(\mathbf{r}) d \mathbf{r}=N$ and $\rho_{t}(\mathbf{r}) \geq 0$, the first HohenbergKohn theorem determines the corresponding external potential $v_{t}(\mathbf{r})$ and via the resulting Hamiltonian the trial wavefunction $\Psi_{t}\left[\rho_{t}(\mathbf{r})\right]$. From the variational energy principle follows that:

$$
\begin{equation*}
E\left[\rho_{t}(\mathbf{r})\right]=\left\langle\Psi_{t}\left[\rho_{t}(\mathbf{r})\right]\right| \hat{H}\left|\Psi_{t}\left[\rho_{t}(\mathbf{r})\right]\right\rangle \geq E_{0}\left[\rho_{0}(\mathbf{r})\right] \tag{3.19}
\end{equation*}
$$

Thus, the ground state energy and density, $\rho_{0}(\mathbf{r})$, can be obtained by minimization of the functional $E[\rho(\mathbf{r})]$ of Eq. (3.17) for arbitrary variations of the density. Unfortunately the functional $F[\rho(\mathbf{r})]$ remains to be unknown.

### 3.2.3 Kohn-Sham Method

As can be seen from the proof of the first Hohenberg-Kohn theorem, the functional $F[\rho]$ is independent of the external potential $v(\mathbf{r})$ and holds for any number of particles. For this reason it is called the universal Hohenberg-Kohn functional. If the exact universal functional $F[\rho]$ was known, DFT would be an exact formulation. However, accurate implementations of DFT are far from easy to achieve because of the unfortunate fact that $F[\rho]$ is hard to approximate in a closed form [181]. The terms that define $F[\rho]$ are the electronic kinetic energy and the electron-electron interaction energy contribution:

$$
\begin{equation*}
F[\rho]=T[\rho]+V_{e e}[\rho]=T[\rho]+J[\rho]+V_{n c}[\rho] \tag{3.20}
\end{equation*}
$$

Here $T[\rho]$ is the kinetic energy functional and $V_{e e}[\rho]$ is a functional that accounts for the electron-electron interaction energy. $V_{e e}[\rho]$ can be split into $J[\rho]$, the classical Coulomb interaction energy and $V_{n c}[\rho]$, that collects all non-classical electron-electron interactions. Among these terms the only one that has an explicit expression is $J[\rho]$, while the explicit form of the other two contributions remains unknown.

A practical solution for the determination of the kinetic energy was provided by Kohn and Sham [182]. Their very clever idea was to realize that if we are not able to accurately determine the kinetic energy through an explicit functional, we should be a bit less ambitious
and concentrate on computing as much as we can of the kinetic energy. Thus, they proposed to introduce orbitals of a non-interacting fictitious reference system from which the major part of the kinetic energy can be computed with good accuracy. The resulting residual, $T_{c}[\rho]$, must be corrected separately:

$$
\begin{equation*}
T[\rho]=T_{s}[\rho]+T_{c}[\rho] \tag{3.21}
\end{equation*}
$$

The subscripts $s$ and $c$ stand for single-particle and correlation, respectively [183]. In the non-interacting system, the single-particle kinetic energy, $T_{s}[\rho]$, is just given by:

$$
\begin{align*}
T_{s}[\rho] & =\langle\Psi[\rho]| \hat{T}|\Psi[\rho]\rangle \\
& =-\frac{1}{2} \sum_{i}^{N}\left\langle\psi_{i}\right| \nabla^{2}\left|\psi_{i}\right\rangle \tag{3.22}
\end{align*}
$$

Note that in Eq. (3.22) $\Psi[\rho]$ denotes the wavefunction of the non-interacting system which is expressed by a single Slater determinant [184] that forms the density $\rho(\mathbf{r})$. The $\psi_{i}(\mathbf{r})$ are the single-particle Kohn-Sham orbitals of the non-interacting system. The fictitious non-interacting system is connected to the real system by the constraint that the occupied Kohn-Sham orbitals generate the ground state density of the real system according to

$$
\begin{equation*}
\rho(\mathbf{r})=\sum_{i}^{N}\left|\psi_{i}(\mathbf{r})\right|^{2} . \tag{3.23}
\end{equation*}
$$

Using Eq. (3.20) and (3.21), the universal functional $F[\rho]$ can be expressed as,

$$
\begin{equation*}
F[\rho]=T_{s}[\rho]+J[\rho]+E_{x c}[\rho], \tag{3.24}
\end{equation*}
$$

whit

$$
\begin{equation*}
E_{x c}[\rho]=T_{c}[\rho]+V_{n c}[\rho] . \tag{3.25}
\end{equation*}
$$

Here, $E_{x c}[\rho]$ is the exchange-correlation functional that contains the kinetic energy difference between the real interacting and fictitious non-interacting system, $T_{c}[\rho]$, and the non-classical

### 3.2. QUANTUM CHEMICAL METHODOLOGY

(quantum-mechanical) electronic interactions $V_{n c}[\rho]$. The energy functional of Eq. (3.17) can be rewritten using Eq. (3.24) as:

$$
\begin{equation*}
E[\rho]=T_{s}[\rho]+J[\rho]+E_{x c}[\rho]+\int v(\mathbf{r}) \rho(\mathbf{r}) d \mathbf{r} \tag{3.26}
\end{equation*}
$$

Eq. (3.26) is formally exact, but $E_{x c}[\rho]$ remains unknown. Since $T_{s}[\rho]$ is not an explicit functional of $\rho(\mathbf{r})$, Eq. (3.26) cannot be directly minimized. However, Kohn and Sham suggested a scheme where the minimization is carried out in an indirect form. To this end, Kohn and Sham related the minimization condition for a fully interacting system with that of a non-interacting system. For the fully interacting system, the minimization condition is given by:

$$
\begin{align*}
\frac{\delta E[\rho]}{\delta \rho(\mathbf{r})} & =\frac{\delta T_{s}[\rho]}{\delta \rho(\mathbf{r})}+\frac{\delta J[\rho]}{\delta \rho(\mathbf{r})}+\frac{\delta E_{x c}[\rho]}{\delta \rho(\mathbf{r})}+v(\mathbf{r})  \tag{3.27}\\
& =\frac{\delta T_{s}[\rho]}{\delta \rho(\mathbf{r})}+v_{H}(\mathbf{r})+v_{x c}(\mathbf{r})+v(\mathbf{r})
\end{align*}
$$

The functional derivative $\frac{\delta J[\rho]}{\delta \rho(\mathbf{r})}$ yields the Coulomb (Hartree) potential, $v_{H}$, and, once an explicit form for $E_{x c}[\rho]$ is chosen, the term $\frac{\delta E_{x c}[\rho]}{\delta \rho(\mathbf{r})}$ yields the exchange-correlation potential, $v_{x c}$.

Consider now a system of non-interacting particles moving in a potential $v_{s}(\mathbf{r})$, the minimization condition is simply:

$$
\begin{equation*}
\frac{\delta E_{s}\left[\rho_{s}\right]}{\delta \rho_{s}(\mathbf{r})}=\frac{\delta T_{s}\left[\rho_{s}\right]}{\delta \rho_{s}(\mathbf{r})}+v_{s}(\mathbf{r}) \tag{3.28}
\end{equation*}
$$

since there are no Hartree and exchange-correlation terms in the absence of interactions. Enforcing the same solution, $\rho_{s}(\mathbf{r}) \equiv \rho(\mathbf{r})$, for Eq. (3.27) and Eq. (3.28) yields for $v_{s}(\mathbf{r})$ :

$$
\begin{equation*}
v_{s}(\mathbf{r})=v_{H}(\mathbf{r})+v_{x c}(\mathbf{r})+v(\mathbf{r}) \tag{3.29}
\end{equation*}
$$

Consequently, one can calculate the density of the interacting system with the external potential $v(\mathbf{r})$ by solving the equation of a non-interacting system with external potential $v_{s}(\mathbf{r})$.

To proceed we now write the Kohn-Sham energy in the following explicit form:

$$
\begin{equation*}
E[\rho]=-\frac{1}{2} \sum_{i}^{N}\left\langle\psi_{i}\right| \nabla^{2}\left|\psi_{i}\right\rangle+\int \rho(\mathbf{r}) v(\mathbf{r}) d \mathbf{r}+\frac{1}{2} \iint \frac{\rho(\mathbf{r}) \rho\left(\mathbf{r}^{\prime}\right)}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} d \mathbf{r} d \mathbf{r}^{\prime}+E_{x c}[\rho] \tag{3.30}
\end{equation*}
$$

Since $F[\rho]$ is universal, $E_{x c}[\rho]$ must be universal too, i.e. it must have the same form for atoms, molecules and solids. However, the actual form of $E_{x c}[\rho]$ is still unsettled. Thus, to describe this term, it is necessary to introduce approximate functionals based on the electron density. Once such a functional is chosen, the minimization of Eq. (3.30) with respect to the Kohn-Sham orbitals, $\psi_{i}$, subject to the orthonormality constraint,

$$
\begin{equation*}
\left\langle\psi_{i} \mid \psi_{j}\right\rangle=\delta_{i j}, \tag{3.31}
\end{equation*}
$$

yields the single-particle Kohn-Sham equations:

$$
\begin{equation*}
\left(-\frac{1}{2} \nabla^{2}+v(\mathbf{r})+\int \frac{\rho\left(\mathbf{r}^{\prime}\right)}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} d \mathbf{r}^{\prime}+v_{x c}[\rho]\right) \psi_{i}(\mathbf{r})=\varepsilon_{i} \psi_{i}(\mathbf{r}) \forall i \tag{3.32}
\end{equation*}
$$

Here $\varepsilon_{i}$ is a Kohn-Sham orbital energy, and $v_{x c}[\rho]$ is known as the exchange-correlation potential, which is defined as the functional derivative of the exchange-correlation energy with respect to the density $\rho(\mathbf{r})$,

$$
\begin{equation*}
v_{x c}[\rho(\mathbf{r})] \equiv \frac{\delta E_{x c}[\rho]}{\delta \rho(\mathbf{r})} \tag{3.33}
\end{equation*}
$$

The above Kohn-Sham equations have to be solved iteratively. They can be casted in matrix form yielding Roothaan-Hall like eigenvalue equations [185, 186]. Details of such formulation are given in the next section.

As described above, the Kohn-Sham method eliminates the unknown kinetic energy functional by introducing orbitals of a fictitious non-interacting reference system. However, the exchange-correlation energy functional is still unknown. In fact, the quality of any DFT calculation using the Kohn-Sham method is determined mainly by the approximation used for the evaluation of $E_{x c}[\rho]$. Different types of approximations for $E_{x c}[\rho]$ have been used, e.g., the

### 3.2. QUANTUM CHEMICAL METHODOLOGY

Local Density Approximation (LDA) in which the Dirac exchange [173] is combined with a fit to the homogeneous electron gas correlation, like the one proposed by Vosko, Wilk and Nusair (VWN) [187]. More sophisticated approaches include the Generalized Gradient Approximations (GGA) [188, 189] like the Becke, Lee, Yang and Parr (BLYP) [190-193], Perdew, Burke and Ernzerhof (PBE) [194] and correct asymptotic potential (CAP-PBE) [195] functionals or hybrid functionals, which include the exact exchange energy density [196] like B3LYP.

The developments of these, and many other, highly accurate density functional approximations have enable an exponentially growing attention to DFT to the point that today Kohn-Sham DFT is the standard tool for electronic structure theory calculations [170].

### 3.2.4 LCGTO Approximation

The Kohn-Sham equations, Eq. (3.32), represent a complicated system of coupled integrodifferential equations (the kinetic energy operator is a differential operator, while the Coulomb contribution is expressed through an integral operator). Therefore, it is necessary to find a computationally efficient way for solving these equations. In principle, a purely numerical approach to solve these equations is possible and a few benchmark calculations for atoms and small molecules using such a technique are available [197]. However, numerical procedures are much too demanding for routine applications and other techniques are required. Therefore, almost all applications of Kohn-Sham density functional theory to finite systems make use of the linear combination of atomic orbitals (LCAO) expansion of the molecular orbitals, $\psi_{i}$.

$$
\begin{equation*}
\psi_{i}(\mathbf{r})=\sum_{\mu} c_{\mu i} \mu(\mathbf{r}) \tag{3.34}
\end{equation*}
$$

In Eq. (3.34) $\mu(\mathbf{r})$ represents an atomic orbital (AO) or, more general, a basis function, and $c_{\mu i}$ a molecular orbital (MO) coefficient. Throughout the text, the basis functions will be denoted with Greek letters. In deMon2k [198, 199] the basis functions are atom-centered (contracted) Gaussian type orbitals (GTO), hence the working ansatz for deMon2k is known as linear combination of Gaussian type orbitals (LCGTO). An unnormalized Cartesian GTO
is given by [200]:

$$
\begin{equation*}
\mu(\mathbf{r})=\left(x-A_{x}\right)^{a_{x}}\left(y-A_{y}\right)^{a_{y}}\left(z-A_{z}\right)^{a_{z}} \sum_{k}^{K} d_{k} e^{-\zeta_{k}(\mathbf{r}-\mathbf{A})^{2}} \tag{3.35}
\end{equation*}
$$

A basis function is completely defined by its atomic center $\mathbf{A}$, its angular momentum vector $\mathbf{a}=\left(a_{x}, a_{y}, a_{z}\right)$, the degree of contraction $K$, the contraction coefficients $d_{k}$ and the orbital exponents $\zeta_{k}$. All these parameters remain constant for a given geometry. By using the LCGTO approximation and assuming a closed-shell system (the extension to the open-shell formalism is straightforward) [201-203], the electronic density is given by:

$$
\begin{equation*}
\rho(\mathbf{r})=2 \sum_{i}^{o c c}\left|\psi_{i}(\mathbf{r})\right|^{2}=2 \sum_{i}^{o c c} \sum_{\mu, \nu} c_{\mu i} c_{\nu i} \mu(\mathbf{r}) \nu(\mathbf{r})=\sum_{\mu, \nu} P_{\mu \nu} \mu(\mathbf{r}) \nu(\mathbf{r}) \tag{3.36}
\end{equation*}
$$

Here the upper sum index "occ" refers to all doubly occupied spatial orbitals in the closedshell system. The $P_{\mu \nu}$ is an element of the closed-shell density matrix defined as:

$$
\begin{equation*}
P_{\mu \nu}=2 \sum_{i}^{o c c} c_{\mu i} c_{\nu i} \tag{3.37}
\end{equation*}
$$

Using the LCGTO expansion for the electron density, the Kohn-Sham energy, Eq. (3.30), can be rewritten as:

$$
\begin{equation*}
E=\sum_{\mu, \nu} P_{\mu \nu} H_{\mu \nu}+\frac{1}{2} \sum_{\mu, \nu} \sum_{\sigma, \tau} P_{\mu \nu} P_{\sigma \tau}\langle\mu \nu \| \sigma \tau\rangle+E_{x c}[\rho] \tag{3.38}
\end{equation*}
$$

The first term of Eq. (3.38) represent the one-electron energy, often named the core energy. The element $H_{\mu \nu}$ contains all one-electron energy contributions, namely the kinetic energy and the nuclear attraction energy of the electrons,

$$
\begin{equation*}
H_{\mu \nu}=-\frac{1}{2}\langle\mu| \nabla^{2}|\nu\rangle-\sum_{A}^{M}\langle\mu| \frac{Z_{A}}{|\mathbf{r}-\mathbf{A}|}|\nu\rangle . \tag{3.39}
\end{equation*}
$$

### 3.2. QUANTUM CHEMICAL METHODOLOGY

The second term in Eq. (3.38) is the two-electron Coulomb repulsion energy, hence the integrals appearing in it are named electron repulsion integrals (ERIs). The short-hand notation used here for the four-center ERIs has the form,

$$
\begin{equation*}
\langle\mu \nu \| \sigma \tau\rangle=\iint \frac{\mu(\mathbf{r}) \nu(\mathbf{r}) \sigma\left(\mathbf{r}^{\prime}\right) \tau\left(\mathbf{r}^{\prime}\right)}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} d \mathbf{r} d \mathbf{r}^{\prime} \tag{3.40}
\end{equation*}
$$

In this ERI notation [204] the double vertical bar || represents the two-electron operator, $1 /\left|\mathbf{r}-\mathbf{r}^{\prime}\right|$. It also separates the functions that depend on the electronic coordinate $\mathbf{r}$ (in the bra), from the functions that depend on the electronic coordinate $\mathbf{r}^{\prime}$ (in the ket). Analog notations will be used for other types of ERIs throughout the text. To derive the Kohn-Sham equations we minimize the energy expression in Eq. (3.38) with respect to the molecular orbitals coefficients under the constraint of molecular orbital orthonormality, Eq. (3.31), which we can write in the form

$$
\begin{equation*}
\left\langle\psi_{i} \mid \psi_{j}\right\rangle=\sum_{\mu, \nu} c_{\mu i} c_{\nu j} S_{\mu \nu}=\mathbf{c}_{i}^{\dagger} \mathbf{S} \mathbf{c}_{j}=\delta_{i j} \tag{3.41}
\end{equation*}
$$

Imposing these constraints in the LCGTO formalism leads to the Lagrange function:

$$
\begin{equation*}
L=E-2 \sum_{i, j}^{\text {all }} \lambda_{i j}\left(\sum_{\mu, \nu} c_{\mu i} S_{\mu \nu} c_{\nu j}-\delta_{i j}\right) . \tag{3.42}
\end{equation*}
$$

The variation of the Lagrange function with respect to the MO coefficients,

$$
\begin{equation*}
\frac{\partial L}{\partial c_{\mu i}}=4 \sum_{\nu}\left(H_{\mu \nu}+\sum_{\sigma, \tau} P_{\sigma \tau}\langle\mu \nu \| \sigma \tau\rangle+\langle\mu| v_{x c}[\rho]|\nu\rangle\right) c_{\nu i}-4 \sum_{j}^{a l l} \sum_{\nu} S_{\mu \nu} c_{\nu j} \varepsilon_{j i} \tag{3.43}
\end{equation*}
$$

must vanish at a stationary point. To obtain Eq. (3.43) the variation of $E_{x c}[\rho]$ is performed using the chain rule:

$$
\begin{equation*}
\frac{\partial E_{x c}[\rho]}{\partial c_{\mu i}}=\int \frac{\delta E_{x c}[\rho(\mathbf{r})]}{\delta \rho(\mathbf{r})} \frac{\partial \rho(\mathbf{r})}{\partial c_{\mu i}} d \mathbf{r}=4 \sum_{\nu}\langle\mu| v_{x c}[\rho]|\nu\rangle c_{\nu i} . \tag{3.44}
\end{equation*}
$$

At this point it is convenient to introduce the Kohn-Sham matrix, $\mathbf{K}$, which represents the variation of the Kohn-Sham energy with respect to the density matrix. Its elements are given by:

$$
\begin{equation*}
K_{\mu \nu} \equiv \frac{\partial E}{\partial P_{\mu \nu}}=H_{\mu \nu}+\sum_{\sigma, \tau} P_{\sigma \tau}\langle\mu \nu \| \sigma \tau\rangle+\langle\mu| v_{x c}[\rho]|\nu\rangle \tag{3.45}
\end{equation*}
$$

Substitution of Eq. (3.45) into Eq. (3.43) under the minimization condition,

$$
\begin{equation*}
\frac{\partial L}{\partial c_{\mu i}}=0 \quad \forall c_{\mu i} \tag{3.46}
\end{equation*}
$$

yields:

$$
\begin{equation*}
\sum_{\nu} K_{\mu \nu} c_{\nu i}=\sum_{j}^{\text {all }} \sum_{\nu} S_{\mu \nu} c_{\nu j} \lambda_{j i} \tag{3.47}
\end{equation*}
$$

Eq. (3.47) is a generalized eigenvalue equation [205] which can be casted into the following matrix equation:

$$
\begin{equation*}
\mathrm{Kc}=\mathrm{Sc} \boldsymbol{\lambda} \tag{3.48}
\end{equation*}
$$

This set of equations have the same form as the famous Roothaan-Hall (RH) equations [185, 186] derived for Hartree-Fock calculations. Because the electronic density is invariant under orthogonal transformations of the occupied molecular orbitals, it is possible (and convenient) to choose a set of molecular orbitals for which the off-diagonal undefined Lagrange multipliers, $\lambda_{i j}$, are zero. Thus, we can use a molecular orbital representation $\mathbf{c} \mathbf{U}$, where $\mathbf{U}$ is an orthogonal transformation matrix, such that $\mathbf{U} \boldsymbol{\lambda} \mathbf{U}^{T}$ becomes a diagonal matrix:

$$
\begin{equation*}
\mathbf{K c U}=\mathbf{S c} \mathbf{U} \underbrace{\mathbf{U}^{\mathrm{T}} \boldsymbol{\lambda} \mathbf{U}}_{\varepsilon} \tag{3.49}
\end{equation*}
$$

These transformed molecular orbitals are called canonical, and they are solutions of the canonical Kohn-Sham equations,

$$
\begin{equation*}
\mathrm{Kc}=\mathrm{Sc} \varepsilon . \tag{3.50}
\end{equation*}
$$

### 3.2. QUANTUM CHEMICAL METHODOLOGY

From now on we will assume that $\mathbf{c}$ are the canonical MO coefficients and, therefore, $\varepsilon$ is a diagonal matrix containing the corresponding orbital energies. As Eq. (3.38) shows, the computation of the full core Hamilton matrix $\mathbf{H}$ scales formally quadratic ( $N^{2}$ ) with the number of basis functions, $N_{\text {bas }}$. The same scaling is observed for the computation of the overlap matrix $\mathbf{S}$. Both matrices, $\mathbf{H}$ and $\mathbf{S}$, remain constant during the whole SCF procedure and, therefore, are computed only once and stored. The Coulomb term, on the other hand, introduces a formal $N_{\text {bas }}^{4}$ scaling into the energy calculation. This contribution is not constant because it depends on $\mathbf{P}$. For the calculation of the exchange-correlation contribution a numerical integration has to be performed. This calculation has a formal $N_{\text {bas }}^{2} \times G$ scaling, where $G$ is the number of grid points necessary to perform the numerical integration. From this discussion follows that calculation of the Coulomb repulsion energy represents the computationally most demanding task in Eq. (3.38). Thus, techniques are needed that reduce the computational work associated to the four-center ERI calculations.

### 3.2.5 Auxiliary Density Functional Theory

### 3.2.5.1 Variational Fitting of the Coulomb Potential

A very popular technique to reduce the formal scaling of computing the two-electron Coulomb repulsion energy is the so-called variational fitting approximation. This technique was introduced by Dunlap and co-workers [206-209], inspired by a former work of Sambe and Felton [210]. It was originally introduced in the deMon-KS [211] and the DGauss [212] programs almost 30 years ago. It is equivalent to the application of the resolution of the identity (RI) [213, 214] for the Coulomb integrals used in other programs, specially from the "wavefunction community". A more extensive discussion of the influence of the variational density fitting technique on electronic structure calculations can be found in the literature [215], [216]. The variational approximation of the Coulomb potential, as implemented in deMon 2 k , is based on the minimization of the following error term:

$$
\begin{equation*}
\mathcal{E}_{2}^{H}=\frac{1}{2} \iint \frac{[\rho(\mathbf{r})-\tilde{\rho}(\mathbf{r})]\left[\rho\left(\mathbf{r}^{\prime}\right)-\tilde{\rho}\left(\mathbf{r}^{\prime}\right)\right]}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} d \mathbf{r} d \mathbf{r}^{\prime} \geq 0 \tag{3.51}
\end{equation*}
$$

The approximated density $\tilde{\rho}(\mathbf{r})$, is expanded as a linear combination of atom centered primitive Hermite-Gaussian type functions [217], $\bar{k}(\mathbf{r})$ :

$$
\begin{equation*}
\tilde{\rho}(\mathbf{r})=\sum_{\bar{k}} x_{\bar{k}} \bar{k}(\mathbf{r}) \tag{3.52}
\end{equation*}
$$

From now on these primitive Hermite Gaussian functions, indicated by a bar, will be called auxiliary functions. An unnormalized auxiliary function, $\bar{k}(\mathbf{r})$, centered on atom A with exponent $\zeta_{\bar{k}}$ has the following form:

$$
\begin{equation*}
\bar{k}(\mathbf{r})=\left(\frac{\partial}{\partial A_{x}}\right)^{\bar{k}_{x}}\left(\frac{\partial}{\partial A_{y}}\right)^{\bar{k}_{y}}\left(\frac{\partial}{\partial A_{z}}\right)^{\bar{k}_{z}} e^{-\zeta_{\bar{k}}(\mathbf{r}-\mathbf{A})^{2}} \tag{3.53}
\end{equation*}
$$

As for the GTOs, all parameters appearing in Eq. (3.53) remain constant during an electronic structure calculation unless the geometry of the molecule is changed. In deMon2k the auxiliary functions are grouped in $s, s p d$ and $s p d f g$ sets sharing the same exponent within each set [218, 219]. In the automatic generation of auxiliary functions [220], indicated by the abbreviation $G E N$, the exponent range for this auxiliary function sets is determined by the smallest, $\zeta_{\text {min }}$, and largest, $\zeta_{\text {max }}$, primitive Gaussian exponent of the basis set used. For the analytic molecular integral calculations with these auxiliary-functions, specially developed integral recurrence relations [217, 221] are used, ensuring high computational performance. Expanding $\rho(\mathbf{r})$ and $\tilde{\rho}(\mathbf{r})$ in Eq. (3.51) in terms of basis and auxiliary functions yields:

$$
\begin{equation*}
\mathcal{E}_{2}^{H}=\frac{1}{2} \sum_{\mu, \nu} \sum_{\sigma, \tau} P_{\mu \nu} P_{\sigma \tau}\langle\mu \nu \| \sigma \tau\rangle-\sum_{\mu, \nu} \sum_{\bar{k}} P_{\mu \nu}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}+\frac{1}{2} \sum_{\bar{k}, \bar{l}} x_{\bar{k}}\langle\bar{k} \| \bar{l}\rangle x_{\bar{l}} \geq 0 \tag{3.54}
\end{equation*}
$$

Since $\mathcal{E}_{2}^{H}$ is positive semi-definite [222] it follows:

$$
\begin{equation*}
\frac{1}{2} \sum_{\mu, \nu} \sum_{\sigma, \tau} P_{\mu \nu} P_{\sigma \tau}\langle\mu \nu \| \sigma \tau\rangle \geq \sum_{\mu, \nu} \sum_{\bar{k}} P_{\mu \nu}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}-\frac{1}{2} \sum_{\bar{k}, \bar{l}} x_{\bar{k}}\langle\bar{k} \| \bar{l}\rangle x_{\bar{l}} \tag{3.55}
\end{equation*}
$$

Note that the equality holds only when $\rho(\mathbf{r})$ equals $\tilde{\rho}(\mathbf{r})$. Thus, any approximate density will provide a lower bound to the true Coulomb repulsion energy. With inequality (3.55) we can

### 3.2. QUANTUM CHEMICAL METHODOLOGY

write a new variational energy expression:

$$
\begin{equation*}
E=\sum_{\mu, \nu} P_{\mu \nu} H_{\mu \nu}+\sum_{\mu, \nu} \sum_{\bar{k}} P_{\mu \nu}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}-\frac{1}{2} \sum_{\bar{k}, \bar{l}} x_{\bar{k}}\langle\bar{k} \| \bar{l}\rangle x_{\bar{l}}+E_{x c}[\rho] \tag{3.56}
\end{equation*}
$$

For short we call this the Kohn-Sham DFT (KS-DFT) approach. In deMon2k, this approach is triggered by the keyword [223] VXCTYPE BASIS because the basis set density, $\rho(\mathbf{r})$, is used for the calculation of the exchange-correlation energy.

The fitting coefficients $x_{\bar{k}}$ are obtained from the minimization of $\mathcal{E}_{2}$ :

$$
\begin{equation*}
\frac{\partial \mathcal{E}_{2}^{H}}{\partial x_{\bar{m}}}=-\sum_{\mu, \nu} P_{\mu \nu}\langle\mu \nu \| \bar{m}\rangle+\sum_{\bar{l}} x_{\bar{l}}\langle\bar{l} \| \bar{m}\rangle \equiv 0 \quad \forall \bar{m} \tag{3.57}
\end{equation*}
$$

At this point it is convenient to introduce the Coulomb matrix, defined as,

$$
\mathbf{G}=\left(\begin{array}{cccc}
\langle\overline{1} \| \overline{1}\rangle & \langle\overline{1} \| \overline{2}\rangle & \ldots & \langle\overline{1} \| \bar{m}\rangle  \tag{3.58}\\
\langle\overline{2} \| \overline{1}\rangle & \langle\overline{2} \| \overline{2}\rangle & \ldots & \langle\overline{2} \| \bar{m}\rangle \\
\vdots & \vdots & \ddots & \vdots \\
\langle\bar{m} \| \overline{1}\rangle & \langle\bar{m} \| \overline{2}\rangle & \ldots & \langle\bar{m} \| \bar{m}\rangle
\end{array}\right)
$$

and the Coulomb vector,

$$
\mathbf{J}=\left(\begin{array}{c}
\sum_{\mu, \nu} P_{\mu \nu}\langle\mu \nu \| \overline{1}\rangle  \tag{3.59}\\
\sum_{\mu, \nu} P_{\mu \nu}\langle\mu \nu \| \overline{2}\rangle \\
\vdots \\
\sum_{\mu, \nu} P_{\mu \nu}\langle\mu \nu \| \bar{m}\rangle
\end{array}\right) .
$$

With $\mathbf{G}$ and $\mathbf{J}$ the following inhomogeneous equation system for the determination of the fitting coefficients, collected in $\mathbf{x}$, can be formulated:

$$
\begin{equation*}
\mathbf{G x}=\mathbf{J} \tag{3.60}
\end{equation*}
$$

A straightforward solution of Eq. (3.60) is obtained by the inversion of the Coulomb matrix G,

$$
\begin{equation*}
\mathbf{x}=\mathbf{G}^{-1} \mathbf{J} \tag{3.61}
\end{equation*}
$$

However the inversion of $\mathbf{G}$ can be numerically unstable if large auxiliary function sets are used. Normalization of the auxiliary functions with respect to the Coulomb norm,

$$
\begin{equation*}
\langle\bar{k} \| \bar{k}\rangle=1 \quad \forall \bar{k} \tag{3.62}
\end{equation*}
$$

ensures certain numerical control of $\mathbf{G}$, nevertheless, $\mathbf{G}$ can still be ill-conditioned. Therefore, deMon2k solves Eq. (3.60) by means of a robust numerical solver based on a quasi Newton method [224].

Once the fitting Eq. (3.60) has been solved, the corresponding Kohn-Sham matrix for a particular density can be obtained as:

$$
\begin{equation*}
K_{\mu \nu}=H_{\mu \nu}+\sum_{\bar{k}}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}+\langle\mu| v_{x c}[\rho]|\nu\rangle \tag{3.63}
\end{equation*}
$$

As Eq. (3.56) shows, the variational fitting of the Coulomb potential replaces the four-center ERI calculation by the corresponding three-center and two-center ERI calculation. The formal scaling for this approach is $N_{\text {bas }}^{2} \times N_{\text {aux }}$, with $N_{a u x} \gtrsim 5 N_{\text {bas }}$. As a result the scaling for the ERI calculation becomes $N_{\text {bas }}^{3}$ with a prefactor greater than 1 . This prefactor can be reduced by taking into account the permutational symmetry of the three-center ERIs. Integral screening, efficient recurrence relations and asymptotic expansion techniques can further improve considerably the computation of three-center Coulomb integrals achieving a near linear scaling [217, 221, 225]. Note that for very large systems sub-linear scaling has also been reported [225, 226]. This leads to an algorithm where the most time-demanding computational step corresponds to the numerical integration of the exchange-correlation potential.

### 3.2. QUANTUM CHEMICAL METHODOLOGY

### 3.2.5.2 Exchange-Correlation Potential from Fitted Density

The use of auxiliary functions for the calculation of the exchange-correlation potential has a long history in DFT methods [210, 227]. In programs like deMon-KS [211] or DGAUSS [212] the exchange-correlation potential is expanded in Cartesian Gaussian functions as proposed by Sambe and Felton [210]. The expansion coefficients are obtained by a least squares fit on a small grid. A serious drawback of this approximation is that neither the fit nor the energy expression are variational and, therefore, reliable forces (and higher order derivatives) cannot be obtained [228, 229]. As an alternative to this approach the direct use of the auxiliary density $\tilde{\rho}(\mathbf{r})$, obtained from the variational fitting of the Coulomb potential, for the calculation of the exchange-correlation energy and potentials was proposed [230-236]. The resulting approximation has been named Auxiliary Density Functional Theory (ADFT) [237]. In deMon2k ADFT is triggered by the keyword [223] VXCTYPE AUXIS. If the auxiliary density is used for the evaluation of the exchange-correlation potential it is desirable that it is positive semi-definite, $\tilde{\rho}(\mathbf{r}) \geq 0$, and integrates to the number of electrons of the system, $\int \tilde{\rho}(\mathbf{r}) d \mathbf{r}=N$.

The normalization to the number of electrons can be included as a constraint in the fitting equations, however, even without this constraint the number of electrons is conserved to high accuracy. The introduction of the positive semi-definiteness property for $\tilde{\rho}(\mathbf{r})$ is less straightforward. Fortunately, regions where $\tilde{\rho}(\mathbf{r})<0$ are rather small and usually occur when $\rho(\mathbf{r}) \approx 0$ [238], therefore, screening of this points does not impact the accuracy of the methodology [232].
The energy expression in ADFT takes the form:

$$
\begin{equation*}
E=\sum_{\mu, \nu} P_{\mu \nu} H_{\mu \nu}+\sum_{\mu, \nu} \sum_{\bar{k}} P_{\mu \nu}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}-\frac{1}{2} \sum_{\bar{k}, \bar{l}} x_{\bar{k}}\langle\bar{k} \| \bar{l}\rangle x_{\bar{l}}+E_{x c}[\tilde{\rho}] \tag{3.64}
\end{equation*}
$$

ADFT is the default method for calculating the exchange-correlation contributions in deMon2k. The variation of this energy expression with respect to density matrix elements
yields the corresponding ADFT Kohn-Sham matrix elements:

$$
\begin{equation*}
K_{\mu \nu}=H_{\mu \nu}+\sum_{\bar{k}}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}+\frac{\partial E_{x c}[\tilde{\rho}]}{\partial P_{\mu \nu}} \tag{3.65}
\end{equation*}
$$

The last term of Eq. (3.65), evaluated analogously to Eq. (3.44), is:

$$
\begin{equation*}
\frac{\partial E_{x c}[\tilde{\rho}]}{\partial P_{\mu \nu}}=\int \frac{\delta E_{x c}[\tilde{\rho}(\mathbf{r})]}{\delta \tilde{\rho}(\mathbf{r})} \frac{\partial \tilde{\rho}(\mathbf{r})}{\partial P_{\mu \nu}} d \mathbf{r}=\sum_{\bar{k}} \frac{\partial x_{\bar{k}}}{\partial P_{\mu \nu}} \int v_{x c}[\tilde{\rho} ; \mathbf{r}] \bar{k}(\mathbf{r}) d \mathbf{r} \tag{3.66}
\end{equation*}
$$

where:

$$
\begin{equation*}
v_{x c}[\tilde{\rho} ; \mathbf{r}] \equiv \frac{\delta E_{x c}[\tilde{\rho}(\mathbf{r})]}{\delta \tilde{\rho}(\mathbf{r})} \tag{3.67}
\end{equation*}
$$

The derivatives of the Coulomb fitting coefficients are obtained using Eq. (3.59) and (3.61) as

$$
\begin{equation*}
\frac{\partial x_{\bar{k}}}{\partial P_{\mu \nu}}=\sum_{\bar{l}} G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| \mu \nu\rangle \tag{3.68}
\end{equation*}
$$

Inserting this result into the Eq. (3.66) yields:

$$
\begin{equation*}
\frac{\partial E_{x c}[\tilde{\rho}]}{\partial P_{\mu \nu}}=\sum_{\bar{k}, \bar{l}}\langle\mu \nu \| \bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\left\langle\bar{l} \mid v_{x c}[\tilde{\rho}]\right\rangle \tag{3.69}
\end{equation*}
$$

To simplify notation, we now introduce the exchange-correlation fitting coefficient vector, $\mathbf{z}$, with elements,

$$
\begin{equation*}
z_{\bar{k}}=\sum_{\bar{l}} G_{\bar{k} \bar{l}}^{-1}\left\langle\bar{l} \mid v_{x c}[\tilde{\rho}]\right\rangle \tag{3.70}
\end{equation*}
$$

The expression for the ADFT Kohn-Sham matrix elements then becomes:

$$
\begin{equation*}
K_{\mu \nu}=H_{\mu \nu}+\sum_{\bar{k}}\langle\mu \nu \| \bar{k}\rangle\left(x_{\bar{k}}+z_{\bar{k}}\right) \tag{3.71}
\end{equation*}
$$

It is important to note that $\mathbf{z}$ is spin-dependent and accounts for the difference between the $\alpha$ and $\beta$ Kohn-Sham matrices in open-shell calculations. Similar to Eq. (3.60), an

### 3.2. QUANTUM CHEMICAL METHODOLOGY

inhomogeneous equation system can be formulated as,

$$
\begin{equation*}
\mathbf{G z}=\mathbf{L}, \tag{3.72}
\end{equation*}
$$

with

$$
\mathbf{L}=\left(\begin{array}{c}
\left\langle v_{x c}[\tilde{\rho}] \mid \overline{1}\right\rangle  \tag{3.73}\\
\left\langle v_{x c}[\tilde{\rho}] \mid \overline{2}\right\rangle \\
\vdots \\
\left\langle v_{x c}[\tilde{\rho}] \mid \bar{m}\right\rangle
\end{array}\right) .
$$

In deMon2k the exchange-correlation fitting coefficients $\mathbf{z}$ are obtained by a pre-conditioned conjugate gradient iterative solver for Eq. (3.72) as proposed by Domínguez-Soria et. al. [224] In order to keep the approach variational, $\tilde{\rho}(\mathbf{r})$ must be taken unaltered from the solution of Eq. (3.61) to calculate $v_{x c}[\tilde{\rho}]$. However this is not mandatory for the calculation of the Coulomb contribution. As a result, there are two sets of fitting coefficients in deMon2k calculations. The first is obtained from the solution of Eq. (3.61) and is used directly for the evaluation of the exchange-correlation potential in order to keep the calculation variational. The other set results from SCF acceleration techniques, such as fitting coefficient mixing [237] or direct inversion in the iterative subspace (DIIS) [237, 239, 240], which are used to build the Coulomb part of the Kohn-Sham matrix.

### 3.2.5.3 Variational Fitting of Exact Exchange Potential

Density-functional theory (DFT) is the most widely used method of modern computational chemistry. All practical implementations of DFT - including the Kohn-Sham formulation (KS-DFT) - rely on approximations to the unknown exchange-correlation functional, typically approximations which are explicit functionals of the density. Unfortunately, the explicit density-dependent approximations for $E_{x c}$ currently available exhibit some important deficiencies, such as the inabilities to properly bind atomic negative ions and describe strongly correlated systems [241-243]. The next step for an improvement is a representation of $E_{x c}$, or least $E_{x}$, in terms of the Kohn-Sham orbitals [182, 242, 244, 245]. In closed-shell systems,
exact exchange, which is equivalent to Fock exchange with Kohn-Sham orbitals, is given by:

$$
\begin{align*}
E_{F} & =-\frac{1}{4} \sum_{\mu, \nu} \sum_{\sigma, \tau} P_{\mu \nu} P_{\sigma \tau}\langle\mu \sigma \| \nu \tau\rangle \\
& =-\sum_{i, j}^{o c c}\langle i j \| i j\rangle \tag{3.74}
\end{align*}
$$

In the variational fitting of the Fock potential, the orbital products,

$$
\begin{equation*}
\rho_{i j}(\mathbf{r})=\psi_{i}(\mathbf{r}) \psi_{j}(\mathbf{r})=\sum_{\mu, \nu} c_{\mu i} c_{\nu j} \mu(\mathbf{r}) \nu(\mathbf{r}), \tag{3.75}
\end{equation*}
$$

are expanded in linear combinations of the same atom-centered primitive Hermite Gaussian auxiliary functions used to approximate the density:

$$
\begin{equation*}
\tilde{\rho}_{i j}(\mathbf{r})=\sum_{\bar{k}} x_{\bar{k} i j} \bar{k}(\mathbf{r}) \tag{3.76}
\end{equation*}
$$

For the variational fitting, the following negative semi-definite error term is maximized:

$$
\begin{equation*}
\mathcal{E}_{2}^{F}=-\sum_{i, j}^{o c c} \iint \frac{\left[\rho_{i j}(\mathbf{r})-\tilde{\rho}_{i j}(\mathbf{r})\right]\left[\rho_{i j}\left(\mathbf{r}^{\prime}\right)-\tilde{\rho}_{i j}\left(\mathbf{r}^{\prime}\right)\right]}{\left|\mathbf{r}-\mathbf{r}^{\prime}\right|} d \mathbf{r} d \mathbf{r}^{\prime} \leq 0 \tag{3.77}
\end{equation*}
$$

Due to the negative semidefinite nature of $\mathcal{E}_{2}^{F}$, the following inequality holds:

$$
\begin{equation*}
-\sum_{i, j}^{o c c}\langle i j \| i j\rangle \leq \sum_{i, j}^{o c c} \sum_{\bar{k}, \bar{l}} x_{\bar{k} i j}\langle\bar{k}||\bar{l}\rangle x_{\bar{l} i j}-2 \sum_{i, j}^{o c c} \sum_{\bar{k}}\langle i j \| \bar{k}\rangle x_{\bar{k} i j} \tag{3.78}
\end{equation*}
$$

The maximization of $\mathcal{E}_{2}^{F}$ corresponds to a minimization of the fitted exact exchange energy given by the right-hand-side of inequality (3.78).

The expansion coefficients $x_{\bar{k} i j}$ are determined by the maximization condition:

$$
\begin{equation*}
\frac{\partial \mathcal{E}_{2}^{F}}{\partial x_{\bar{k} i j}}=\sum_{i, j}^{o c c}\langle i j||\bar{k}\rangle-\sum_{i, j}^{o c c} \sum_{\bar{l}}\langle\bar{k}||\bar{l}\rangle x_{\bar{l} i j} \equiv 0 \forall \bar{k}, i, j . \tag{3.79}
\end{equation*}
$$

### 3.2. QUANTUM CHEMICAL METHODOLOGY

From Eq. (3.79) one can cast a set of inhomogeneous equation systems, one for each orbital product, which in matrix notation takes the form:

$$
\begin{equation*}
\mathbf{G} \mathbf{x}_{i j}=\mathbf{J}_{i j} \forall i, j \tag{3.80}
\end{equation*}
$$

Here $\mathbf{x}_{i j}$ collects the fitting coefficients for each orbital product and $\mathbf{J}_{i j}$ is defined as

$$
\mathbf{J}_{i j}=\left(\begin{array}{c}
\langle i j||\overline{1}\rangle  \tag{3.81}\\
\langle i j||\overline{2}\rangle \\
\vdots \\
\langle i j \| \bar{m}\rangle
\end{array}\right)
$$

After the fitting equations have been solved, the fitted exact exchange energy can be written in a more compact form as:

$$
\begin{align*}
\tilde{E}_{F} & =-\sum_{i, j}^{o c c} \sum_{\bar{k}, \bar{l}} x_{\bar{k} i j} G_{\bar{k} \bar{l}} x_{\bar{l} i j}  \tag{3.82}\\
& =-\sum_{i, j}^{o c c} \sum_{\bar{k}, \bar{l}}\langle i j \| \bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| i j\rangle \tag{3.83}
\end{align*}
$$

The total hybrid ADFT energy thus becomes

$$
\begin{align*}
E= & \sum_{\mu, \nu} P_{\mu \nu} H_{\mu \nu}+\sum_{\bar{k}} \sum_{\mu, \nu} P_{\mu \nu}\langle\mu \nu \| \bar{k}\rangle x_{\bar{k}}-\frac{1}{2} \sum_{\bar{k}, \bar{l}} x_{\bar{k}} x_{\bar{l}}\langle\bar{k} \| \mid \bar{l}\rangle+ \\
& (1-\alpha) E_{x}[\tilde{\rho}]-\alpha \sum_{i, j}^{o c c} \sum_{\bar{k}, \bar{l}}\langle i j \| \bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| i j\rangle+E_{c}[\tilde{\rho}], \tag{3.84}
\end{align*}
$$

where the exchange-correlation energy has been explicitly separated. Eq. (3.84) is only an example of how to build a hybrid functional, and, in practice, more than one mixing parameter can be found in a hybrid definition. Variation of Eq. (3.84) with respect to the
molecular orbital coefficients under the orthonormality constraint, Eq. (3.31), yields

$$
\begin{align*}
\frac{\partial E}{\partial c_{\mu i}} & =4 \sum_{\nu}\left(H_{\mu \nu}+\sum_{\bar{k}}\langle\mu \nu \| \bar{k}\rangle\left(x_{\bar{k}}+z_{\bar{k}}\right)-\alpha \sum_{j}^{o c c} \sum_{\bar{k}, \bar{l}}\langle\mu j \| \bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| j \nu\rangle\right) c_{\nu i}  \tag{3.85}\\
& -4 \sum_{\nu} \sum_{j} S_{\mu \nu} c_{\nu j} \epsilon_{j i}
\end{align*}
$$

with

$$
\begin{equation*}
z_{\bar{k}}=\sum_{\bar{l}} G_{\bar{k} \bar{l}}^{-1}\left\langle\bar{l} \mid(1-\alpha) v_{x}[\tilde{\rho}]+v_{c}[\tilde{\rho}]\right\rangle \tag{3.86}
\end{equation*}
$$

The corresponding Kohn-Sham matrix elements are defined as

$$
\begin{equation*}
K_{\mu \nu}=H_{\mu \nu}+\sum_{\bar{k}}\langle\mu \nu \| \mid \bar{k}\rangle\left(x_{\bar{k}}+z_{\bar{k}}\right)-\alpha \sum_{j}^{o c c} \sum_{\bar{k}, \bar{l}}\langle\mu j \| \bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| \mid j \nu\rangle . \tag{3.87}
\end{equation*}
$$

The implementation of Eq. (3.83) and Eq. (3.87) leads to an algorithm that scales as $N_{o c c} \times N \times M^{2}$. Many groups have proposed modifications to the variational exact exchange fitting method giving rise to algorithms like atomic resolution of the identity [246], local density fitting (LDF) [247, 248], pair atomic resolution of the identity [249-251], as well as atom-centered Cholesky decomposition approaches [252]. The recently developed LDF approach to exact exchange (LDF-EXX) implemented in deMon2k [248] is based on the fact that the exact exchange contribution to the Kohn-Sham matrix,

$$
\begin{equation*}
-\alpha \sum_{j}^{o c c} \sum_{\bar{k}, \bar{l}}\langle\mu j||\bar{k}\rangle G_{\bar{k} \bar{l}}^{-1}\langle\bar{l} \| j \nu\rangle, \tag{3.88}
\end{equation*}
$$

is invariant under unitary transformations of the molecular orbitals. Thus, any set of molecular orbitals generated through orbital localization procedures, like Edmiston-Ruedenberg [253], Foster-Boys [254], or Pipek-Mezey [255], can be used to calculate the exact exchange contribution. By using localized molecular orbitals, the three-center ERIs appearing in Eq. (3.88) have non-negligible values only when atomic orbitals $\mu(\mathbf{r})$ and $\nu(\mathbf{r})$ are closed in space to the localized molecular orbital $\psi_{j}(\mathbf{r})$. This allows the difinition of local sets of basis functions around each localized molecular orbital and the screening of a large number or integrals.

### 3.2. QUANTUM CHEMICAL METHODOLOGY

Since all orbitals products $\psi_{j}(\mathbf{r}) \mu(\mathbf{r})$ are also localized in space, the auxiliary functions needed to accurately fit these products can also be restricted to a region closed to $\psi_{j}(\mathbf{r})$. In this way, local auxiliary function sets can be defined for each localized molecular orbital. For sufficiently large systems, the size of the local sets remain constant, reducing the scaling to $N_{\text {occ }}$ with an $N_{\text {local }} \times M_{\text {local }}^{2}$ constant prefactor [256]. Another consequence of the localization is that each localized molecular orbital has a particular Coulomb matrix. The computational cost for computing all these local $\mathbf{G}$ and $\mathbf{G}^{-1}$ matrices for all occupied localized molecular orbitals is in larger systems more than overcompensated by the reduced dimensionality of these matrices.

## Chapter 4

## Computational Methodology

Among the hundreds, or even thousands, of different isomers that can be generated for a given number of carbon atoms, only one, maybe two and sometimes three are usually found to encapsulate a cluster forming a new EMF. Therefore, structural elucidation by X-ray diffraction (along with other characterization techniques, such as IR and Raman spectroscopies, etc.) is the final and conclusive step for the precise determination of the isomeric structure of the carbon cages. It is necessary to clarify that for a complete elucidation of the structure, the determination of the carbon cage isomer as well as the geometry and position of the encapsulated cluster must be achieved. However, there is a major obstacle that causes difficulties in the experimental structural assignments: The low yield obtained for most of these species. For this reason the combination of theoretical studies with the experimental ones is of major importance to obtain correct geometrical and electronic structure assignments [15].

### 4.1 Working Strategy

In order to design an effective computational strategy for the structure determination of endohedral metallofullerenes in this thesis, the following most important factors that control the selection of a specific cage over all the different isomers were taken into account: (i) the electron transfer from the trapped unit to the carbon cage; and (ii) the geometry of the endohedral cluster and the cage, as well as the interaction between them. Figure 4.1 shows
schematically the computational strategy proposed in this work, which is formed by three main stages.

After the experimental detection, usually from mass spectrometry data, it is possible to know how many carbon atoms the synthesized fullerene possesses. With this information the number of possible isomers and their assignment as IPR or non-IPR isomers is possible. Thus, the first stage in our work strategy is the computation of the relevant empty cages, followed by the computation of the hosted clusters and finally, the computation of the EMF structures. Each stage of this work strategy will be described in more details in this chapter.

Figure 4.1: Computational protocol designed in order to elucidate the structure of endohedral metallofullerenes. Empty cage (left), endohedral clusters (middle) and EMF system (right).

The work path shown in Figure 4.1 was followed throughout the whole thesis to propose a cage candidate and support the structure elucidation of the synthesized metallofullerenes.

### 4.2 Computation of Empty Fullerene Cages

### 4.2.1 Cage and Fullerene Codes

The first task consists in the generation of the relevant fullerene cage isomers using the CaGe program [137]. Note that the output of this program is a single file containing all the generated structures (listed one after the other) which can be, if requested, only IPR structures, or both, IPR and non-IPR structures (default setting). Additionally, for fullerenes of $\mathrm{C}_{n}, n \leq 100$ the CaGe program offers the option to sort the generated structures according to the order of the

### 4.2. COMPUTATION OF EMPTY FULLERENE CAGES

Atlas of Fullerenes. Unfortunately, the necessary information for the unequivocally labeling of the fullerene cage isomers, such as the isomer numbers according to the Atlas of Fullerene [29] (for $\mathrm{C}_{n}$ fullerenes with $n>100$ ), the cage symmetry and the number of pentagon-pentagon fusions (5-5 fusions, APP, adjacent pentagon pairs) in a given fullerene, are not provided by the CaGe program. Therefore, the CaGe generated fullerene structures are further analyzed with the FULLERENE program [257], in order to obtain these relevant information.

In some cases the CaGe outputs can be very large. For example, when IPR structures are generated for the $\mathrm{C}_{106}$ fullerene cage, 1233 sets of coordinates are listed in the same output file. Thus, an automatized processing is needed. For the sake of simplicity, we describe in the following this process for the generation of the 5 IPR isomers of the $\mathrm{C}_{78}$ fullerene cage. In a first step, the fullerene coordinates from the CaGe output are copied into individual files and augmented by an input header for the FULLERENE program as depicted in Figure 4.2. For this task a Python script was created.

```
This is a generated xyz input to be used in Fullerene

```

Figure 4.2: Example of an automatically generated FULLERENE input from a CaGe output for the $\mathrm{C}_{78}$ fullerene.

In Figure 4.2, the first line is a comment line while the following ones, starting with the \& symbol, are FULLERENE commands indicating how many atoms ( 78 carbon atoms in this example) have to be read and in which format (ICart=1 for Cartesian) they are specified. The rest of the listed commands in Figure 4.2 are without further options, because they are not relevant for our analysis. However, they must be specified in the FULLERENE input in order to ensure the correct execution of the program. After the FULLERENE commands the Cartesian coordinates of the carbon atoms are given in the depicted input file of Figure
4.2. Each atomic coordinate triple is led by the corresponding atomic number, here 6 for the carbon atom.

In order to show the extracted information from the FULLERENE outputs, useful for the characterization and labeling of the isomer structures, the output files of the 5 IPR isomers of the $\mathrm{C}_{78}$ fullerene cage are taken as an example. From each FULLERENE output file, we extract the following information (see Figure 4.3): The number of pentagon-pentagon fusions, with which we can verify if the isomer accomplishes IPR or not; The symmetry of the isomer, with which it is possible to label the structure; The spiral list of pentagon positions, that permits the assignment of the isomer number according to the Atlas of Fullerenes. This 12-number string is searched in a FULLERENE reference file containing the spiral list of pentagon positions for all possible isomers of a given fullerene. The line number where both strings match is taken as the isomer number according to the Atlas of Fullerenes [29]. This data together with the symmetry allow us the labeling of the fullerene isomers, according to the nomenclature used in this thesis. Thus, for the example in Figure 4.2, the isomer is labeled as $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$.

Figure 4.3: Relevant information extracted from the five generated FULLERENE outputs for the $\mathrm{C}_{78}$ fullerene cages.

With the generated structures and the obtained information from the programs CaGe and FULLERENE, we have a set of isomers to work with. The next step is their structure

### 4.2. COMPUTATION OF EMPTY FULLERENE CAGES

optimization. The structures generated by the CaGe program are used as inputs for these local optimizations which according to their energetics, will narrow down the set of suitable isomers for the possible parent cage of the EMF system.

### 4.2.2 Optimization of the Empty Fullerene Cages

When optimizing fullerene cages for the structure elucidation of EMFs some aspects have to be taken into account. First, one of the specific features of endometallofullerenes is that their parent cages are usually energetically high lying isomers of the corresponding empty fullerenes, that is, the stability of EMFs often follows the energetic trends of anionic fullerenes, rather than that of neutral cages [258]. This can be understood within the ionic model [52, 259], which considers that there is a formal transfer of electrons from the encapsulated atoms or cluster to the carbon cage, thus, describing the EMFs as metal cations encapsulated in negatively charged carbon cages ([cluster $]^{m+} @\left[C_{2 n}\right]^{m-}$ ). These ideas are supported by computational studies [6, 260] that showed that the cage isomerism of EMFs is largely determined by the formal charge of the fullerene, and that the lowest energy isomer may differ when changing this formal charge. For example, in Figure 4.4 our ADFT calculations show that the most stable isomer of neutral $\mathrm{C}_{78}$ is $\mathrm{C}_{2 \mathrm{v}}-24107$ (black rhombus), whereas for the di-, tetra- and hexaanionic $\mathrm{C}_{78}$ the isomer $\mathrm{D}_{3 \mathrm{~h}}-24109$ (blue circles) is lowest in energy. Note also that the non-IPR $\mathrm{C}_{2}$-22010 (pink triangles) isomer is considerably more stable than other IPR isomers in the hexaanionic state. According to the previous ideas, the anionic empty cages can be used as a guide to predict the most suitable isomer for specific endohedral fullerene systems [261, 262].

Although the cage stability is very important, it is not the only aspect one must have in mind when determining the structure of endometallofullerenes. The cage should also provide a suitable shape to enclose metal atoms or clusters; that is, there should be enough space in the cage for the endohedral species [6]. It has been shown that as the metallic radii increases the size of the preferred cages also increases [263, 264]. However, this is not always fulfilled. Take as example, $\mathrm{Sc}_{3} \mathrm{~N}$ and $\mathrm{Gd}_{3} \mathrm{~N}$ which prefer the $\mathrm{C}_{80}$ cage for encapsulation.

Figure 4.4: Variation in the order of stability of $\mathrm{C}_{78}$ isomers as function of net charge. Each colored symbol represents the energy of a given isomer, in kcal/mol, relative to that of the most stable one for a given charge. To guide the eye, data points are connected by straight lines.

Nevertheless, they have also be found in smaller cages, such as $\mathrm{C}_{68}$ and $\mathrm{C}_{78}$, respectively [265-267]. Interestingly, all these smaller cages that can encapsulate $\mathrm{Sc}_{3} \mathrm{~N}$ and $\mathrm{Gd}_{3} \mathrm{~N}$ possess adjacent pentagon pairs. Therefore, in addition to the stabilization provided by the charge transfer, there is an important effect due to the interaction of the cluster and the cage $[6$, 107]. This effect is critical when the cages show fused pentagons in the carbon framework. If we think about the charge distribution over the cage, the pentagon-pentagon fusions are nucleophilic regions. The trapped metals are formally cations (since they transfer charge to the cage) resulting in a favourable interaction between the two moieties [107]. For example, when the metal in a non-IPR endohedral fullerene is coordinated to the pentagon pair, it donates two electrons to the pentalene unit to make it aromatic [268]. This argumentation is in line with the fact that the maximum number of pentagon pairs found in endohedral fullerenes is equal to half the formal charge of the cage: Three pairs for hexaanionic cages as in $\mathrm{Sc}_{3}{\mathrm{~N} @ \mathrm{C}_{68}}^{\text {[265] }}$ or $\mathrm{Sc}_{3} \mathrm{~N} @ \mathrm{C}_{70}$ [115], two pairs for tetraanionic cages as in $\mathrm{Sc}_{2} \mathrm{C}_{2} @ \mathrm{C}_{68}$ [269], and one pair for diaanionic cages as in $\mathrm{Ca} @ \mathrm{C}_{72}$ [52]. Therefore, in this step, the screening for the metallofullerene structure begins by considering the neutral as well as the anionic empty cages (IPR and possible non-IPR). Once these neutral and charged empty cages have been

### 4.3. COMPUTATION OF THE ENDOHEDRAL CLUSTERS

optimized, the following step is the selection of the lowest-energy isomer structure, usually in a range of around $20 \mathrm{kcal} / \mathrm{mol}$ as candidates for the parent cage of the EMF system.

### 4.3 Computation of the Endohedral Clusters

The cluster geometry also plays an important role for the structure assignment of the endometallofullerene. The analysis of the encapsulated cluster configurations reveals structures in which the metal atoms are maximal separated in order to minimize their electrostatic repulsion. Popov and co-workers [270] showed that each cluster has an ideal geometry (distance and angles) and that some energy penalty appears when the cluster is distorted in order to fit into the carbon cage. Therefore, there exist optimal combinations that allow the clusters to have geometries closed to the ideal ones and, at the same time, allow a strong interaction between cluster and cage, that will lead to the most stable endometallofullerene structure. Hence, in this step of our working strategy, the structure of the endohedral clusters is optimized starting from different configurations and spin multiplicities. From these computations, the lowest-energy cluster structure will be selected to be introduced into the empty fullerene cages to form the corresponding endometallofullerenes.

### 4.4 Computation of the EMF Structures

It is important to keep in mind that for a complete structural characterization, not only the elucidation of the fullerene isomer is needed but also the position and geometry of the internal guest. Even when in the previous step the lowest-energy structure of the cluster was found, its geometry can change during the optimization of the complete EMF system. For this reason, once the optimized cluster has been introduced into the empty fullerene isomer(s) (selected according to section 4.2), local optimizations will be carried out employing different spin multiplicities. From these calculations the spin multiplicity is determined by the lowest energy structure. With this structure as starting point, a mass-scaled firstprinciple Born-Oppenheimer molecular dynamics (BOMD) simulation will be performed and
the resulting trajectory will be analyzed with the aim to explore different orientations and geometries that the cluster can adopt inside the carbon cage. For the mass-scaled BOMD simulations, the GGA level of theory by means of the PBE exchange-correlation functional, is employed. The temperature for these calculations is set to 1200 K , and a step size of 1 fs and trajectory lengths of 14000 fs is used. From the mass-scaled BOMD trajectories we select most stable structures that are well separated from each other. These structures are taken as starting points for local optimizations. After carrying out these optimizations, frequency analyses are performed in order to characterize the found minima. To bridge to experiment we also computed the IR and Raman spectra of these minima employing the double harmonic approximation.

## Chapter 5

## Methodology Validation

In order to assess our methodology for the theoretical study of actinide EMFs, the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system was used for validation because experimental and theoretical studies are available [17, $24,25]$. To this end, the outlined working strategy was applied, in order to elucidate the isomer structure of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system.

All calculations were performed with the DFT program deMon2k [198, 271]. The ADFT and KS-DFT approaches, described in Chapter 3, were employed. For the calculation of the exchange-correlation energy and potential the generalized gradient approximation from Perdew, Burke and Ernzerhof (PBE) [194] and its hybrid analog [272, 273] were used. The GGA optimized DZVP all electron basis set [220] was used for the carbon whereas for uranium the quasi-relativistic (QECP) [274] and relativistic (RECP) [275] small-core pseudopotentials from the Stuttgart-Dresden group in combination with corresponding energy-optimized double-zeta [276] and correlation consistent triple-zeta [277] valence basis sets were employed. For the fitting of the density the automatically generated auxiliary function sets [220, 278] GEN-A $n$ and GEN-A $n^{*}$, with $n=2$, and GEN-A $n^{* *}$, with $n=2,4$, were used. The latter was developed during this work because the GEN-A2* auxiliary function set turned out to be insufficient for the accurate description of the uranium dimer. These automatically generated auxiliary functions are provided in deMon2k by means of the auxiliary function specification GEN-A $n$, with $n=1,2,3,4$, and GEN-A $n^{*}$, with $n=2,3,4$. The GEN-A1 set possess only $s$ auxiliary functions, and for the purpose of this work is not employed in our calculations. The

GEN-A $n$ sets consist of $s, p$, and $d$ Hermite Gaussian functions. In addition the GEN-A $n^{*}$ also have $f$ and $g$ Hermite Gaussians. The extended GEN-A2** auxiliary function set builds on the GEN-A2* set and includes also $h$ and $i$ Hermite Gaussian auxiliary functions. Table 5.1 lists the exponents and function sets for the GEN-A2, GEN-A2* and GEN-A2** auxiliary function sets, generated based on the aforementioned QECP and RECP valence basis sets for the uranium atom. Note that the range of exponents of all auxiliary functions is determined by the smallest and largest primitive Gaussian exponent of the chosen basis set. Therefore changing the valence basis set, will also change the generated auxiliary function sets.

Table 5.1: Exponents and auxiliary function set structure for the uranium valence basis sets of the QECP and RECP pseudopotentials.

For all the calculated structures, a full geometry optimization without any symmetry restriction was performed using a quasi-Newton optimization method in delocalized internal coordinates [279]. A frequency analysis was carried out to ensure optimization to a minimum.

### 5.1. URANIUM ATOM AND DIMER

The second derivatives were calculated by analytic second differentiation of the ADFT energy at the optimized geometry [280]. The harmonic frequencies were obtained by diagonalizing the mass-weighted Cartesian force constant matrix.

### 5.1 Uranium Atom and Dimer

The methodology validation was started by studying the uranium atom. The atomic ground state of the uranium atom is reported as ${ }^{5} \mathrm{~L}_{6}$ with the electronic configuration $7 s^{2} 5 f^{3} 6 d^{1}$. Its first excited state is assigned as ${ }^{7} \mathrm{M}_{6}$ with the electronic configuration $7 s^{1} 5 f^{3} 6 d^{2}$. The experimental energy difference between these two electronic states is $17.8 \mathrm{kcal} / \mathrm{mol}$ [281]. As Table 5.2 shows the calculated excitation energies between the quintet and septet electronic state are in reasonable agreement with the experimental result when GEN-A2*, GEN-A2** and GEN-A4** auxiliary functions are used in combination with both pseudopotentials and their corresponding valence basis sets. A more detailed inspection of the results reveals that the differences between ADFT and KS-DFT approaches become smaller as the auxiliary function set increases. In other words, the results become more consistent between both approaches, when the GEN-A2** and GEN-A4** auxiliary function sets are used.

Table 5.2: Calculated excitation energy and ionization potentials [in kcal/mol] of the uranium atom.

The experimental and calculated ionization potentials are shown in Table 5.2, too. The results show consistency between both, ADFT and KS-DFT approaches. Best agreement
with the experimental values, is obtained with the GEN-A2** and GEN-A4** auxiliary function sets in combination with both pseudopotentials and their corresponding valence basis sets. Another important feature to note is that these calculated values at the singledeterminant level of theory compare favorable with those obtained at higher levels of theory, like complete active space self-consistent field (CASSCF) or multi-reference averaged coupledpair functional (ACPF) as shown in Table 5.2.

In the following validation, the ground state structure of the $U_{2}$ molecule was studied. To this end we optimized this dimer with several spin multiplicities. The only experimental data available on neutral $\mathrm{U}_{2}$ is the dissociation energy of $52 \pm 5 \mathrm{kcal} / \mathrm{mol}$ [284]. This value was obtained at temperatures in the range of $2500-2700 \mathrm{~K}$ under the assumption of a bond length of $3.0 \AA$. On the other hand, some theoretical studies have been published so far. The first attempt to study the $U_{2}$ dimer using correlated electronic structure theory was reported by Pepper et al. in 1990 [285], resulting in a quintet spin multiplicity ground state with a bond distance of $2.2 \AA$. Then, Gagliardi et al. [286] employing the CASSCF method adding dynamic correlation energy using second order perturbation theory (CASSCF/CASPT2), initially reported a septet ground state structure with an equilibrium bond distance of 2.43 $\AA$ and a dissociation energy of $40.2 \mathrm{kcal} / \mathrm{mol}$, which decreased to $30.5 \mathrm{kcal} / \mathrm{mol}$ when the effect of spin-orbit coupling was added [286].

However, in a subsequent publication the authors reported an exited septet state only 80 $\mathrm{cm}^{-1}(0.23 \mathrm{kcal} / \mathrm{mol})$ above the ground state. Dissociation energies of 26.5 and $26.3 \mathrm{kcal} /-$ mol along with bond distances of 2.43 and $2.46 \AA$ were reported, respectively, for these two states. Therefore, the authors state that it is impossible from these studies to unequivocally determine the ground state of $\mathrm{U}_{2}$ [287]. Both studies were performed employing the double-zeta atomic natural orbital basis set, which includes scalar relativistic effects using the Douglas-Kroll-Hess Hamiltonian.

Very recently, a relativistic multiconfigurational study, employing the extended restricted active space self-consistent field (RASSCF) method was published [288]. It reports a septet ground state with an equilibrium bond distance of $2.56 \AA$ and a dissociation energy of 21 $\mathrm{kcal} / \mathrm{mol}[288]$. The reported data were obtained with the relativistic triple-zeta basis set

### 5.1. URANIUM ATOM AND DIMER

using the Dirac-Coulomb-Gaunt Hamiltonian.
Table 5.3 and 5.4 list the $\mathrm{PBE} / \mathrm{QECP}$ and $\mathrm{PBE} / \mathrm{RECP}$ results of this work in combination with different auxiliary function sets (GEN-A2, GEN-A2*, GEN-A2** and GEN-A4**), employing the ADFT and KS-DFT approaches. From these results, it can be seen that employing GEN-A2** and GEN-A4** auxiliary function sets yield septet spin multiplicity ground states, independent from the employed methodology. This result is in agreement with the previously reported multiconfigurational data [286, 288].

Table 5.3 also shows that employing the QECP and its corresponding double-zeta valence basis set in combination with the GEN-A2* auxiliary function set, two different ground state spin multiplicities are found. Within the ADFT approach, a septet spin multiplicity ground state is obtained, while for the case of the KS-DFT approach, the spin multiplicity with the lowest energy is an oncet. Interestingly to note, the same trend is observed for RECP calculations employing a triple-zeta valence basis set (see Table 5.4).

Moreover, it is also observed that the bond distances and relative energies values become consistent between both, ADFT and KS-DFT approaches, with the GEN-A2** auxiliary function set. Note the marked difference to the GEN-A2 auxiliary function set calculations in which ADFT and KS-DFT results differ significantly. In fact, such consistency and improvement in the obtained results could be due to a better description of the auxiliary density for this actinide, due to the inclusion of $h$ and $i$ Hermite Gaussian auxiliary functions in the extended GEN-An** auxiliary function sets. Due to the obtained results, we conclude that the GEN-A2 ${ }^{* *}$ auxiliary function set must be used for a consistent description of the uranium atom and dimer.

Additionally, our ADFT calculations are also in good agreement with a previously reported DFT study using the GGA B88-P86 exchange correlation functional with the quasirelativistic small-core pseudopotential and its corresponding double-zeta valence basis set. In this study, the authors report a septet ground state with a bond length of $2.27 \AA$ for the $\mathrm{U}_{2}$ dimer [289].

Table 5.3: Relative energies $\Delta \mathrm{E}$, in $\mathrm{kcal} / \mathrm{mol}$, and equilibrium distances $\mathrm{r}_{e}$, in $\AA$, employing different auxiliary function sets for the uranium dimer with different spin multiplicities. Dissociation energies $\left(\mathrm{D}_{e}\right)$ are given in $\mathrm{kcal} / \mathrm{mol}$. Bold values in parentheses correspond to single point dissociation energies calculated with PBE0 on top of the PBE optimized dimer.

From our calculations it was also found that PBE in combination with both small-core pseudopotentials overestimates the binding energy as shown in Table 5.3 and 5.4. Structure optimizations with PBE0 [272, 273], yield an oncet ground state. This is in accordance with the general experience that hybrid functionals stabilize high spin ground states [290]. However, PBE0 single point energy calculations on top of the PBE optimized geometries improve the pure GGA calculated values of the dissociation energy, as it can be seen from the bold values shown in parentheses in Table 5.3 and 5.4.

The results of single point energy calculations on top of the PBE optimized structures using global (PBE0 [272, 273] and B3LYP [291]) and range-separated hybrid functionals (LCPBE [194, 292], CAMPBEO [293], HSE06 [294] and CAMB3LYP [295]) in combination

### 5.2. EMPTY $\mathrm{C}_{80}$ FULLERENE CAGE

Table 5.5: Dissociation energies obtained with hybrid functionals using the PBE optimized structure of the uranium dimer. All values are in $\mathrm{kcal} / \mathrm{mol}$.

| Functional | QECP | RECP |
| :--- | :---: | :---: |
| PBE0 | 47.00 | 48.31 |
| CAMPBE0 | 47.22 | 47.74 |
| LCPBE | 76.41 | 73.04 |
| HSE06 | 43.40 | 44.70 |
| B3LYP | 31.14 | 31.72 |
| CAMB3LYP | 21.75 | 23.00 |

with the GEN-A2** auxiliary functions set, are listed in Table 5.5.
Our results for the uranium dimer can be summarized as follows. The ADFT and KSDFT calculations yield consistent results, when the GEN-An** auxiliary function sets are used albeit with a reduced computational demand for ADFT. Moreover the GGA calculations predict, in agreement with other theoretical studies, a septet ground state. However, according to the reported 2.43 [286] and $2.56 \AA$ [288] U-U bond distances, our calculated bond length of $2.30 \AA$ is considerable shorter. The GGA methodologies tend to overestimate severely the dissociation energy, compared to the reported values that are available up to now. Optimization with hybrid functionals yield ground states with higher spin multiplicities [290]. Single point energy calculations with global and range-separated hybrid functionals on top of the PBE optimized structures, significantly reduce the dissociation energy. In particular, with the range-separated CAMB3LYP hybrid functional dissociation energies in the same range as from multiconfigurational wave function methods are obtained.

### 5.2 Empty C 80 Fullerene Cage

Following the outlined working strategy, the next step is the study of the seven empty IPR fullerene cages of the $\mathrm{C}_{80}$. We are going to focus solely on IPR isomers, because previous experimental and theoretical studies showed that only these types of fullerene cages are relevant for $\mathrm{U}_{2} @ \mathrm{C}_{80}$. Several earlier theoretical studies have addressed the stability of the $\mathrm{C}_{80}$ isomers and different results were obtained. A tight-binding molecular-dynamics (TBMD)
study on $\mathrm{C}_{80}$ predicted the $\mathrm{D}_{5 \mathrm{~h}}-6$ isomer as ground state [296]. Calculations using combinations of semiempirical methods and subsequent ab-initio single-point calculations as well as full ab-initio structure optimizations and energy calculations predicted the $D_{5 d}-1$ and $D_{2}-2$ isomers as most stable structures. [297-307]. Experimentally, only two isomers, $\mathrm{D}_{5 \mathrm{~d}}-1$ and $D_{2}-2$, have been obtained and characterized as empty molecules, with a $D_{2}-2$ to $D_{5 d}-1$ ratio of $30: 1$ [308, 309].

Table 5.6 lists relative energies employing the local density approximation (LDA), in form of VWN [187], and the generalized gradient approximation (GGA), in form of PBE. We chose here the PBE functional because it was also used successfully for the calculations of the uranium atom and dimer. Both, LDA and GGA approximations are evaluated within the ADFT and KS-DFT approaches in combinations with the DZVP basis and the GEN-A2 as well as GEN-A2* auxiliary function sets. As Table 5.6 shows, VWN and PBE both predict as the lowest-energy structure, the $\mathrm{D}_{5 \mathrm{~d}}-1$ isomer. Moreover, as can be seen from this table, the relative ADFT and KS-DFT energies become consistent when the GEN-A2* auxiliary function set is employed. Note that the calculations performed within KS-DFT took more than twice as long as those with the ADFT approach. Due to these results, all the following calculations were performed with the GEN-A2* auxiliary function set and within the ADFT approach.

Table 5.6: Relative energies ( $\Delta \mathrm{E}$, in $\mathrm{kcal} / \mathrm{mol}$ ) for neutral $\mathrm{C}_{80}$ fullerene cages as obtained from different theoretical methodologies.

### 5.2. EMPTY $\mathrm{C}_{80}$ FULLERENE CAGE

Further calculations varying basis set and functional were performed for the $\mathrm{C}_{80}$ IPR fullerene cages and are summarized in Table 5.7. For comparison with available literature data we performed structure optimizations with the TZVP basis set, with the B3LYP functional and the $6-31 G^{*}$ Hartree-Fock optimized basis set as well as single point energy calculations with the $6-311 \mathrm{G}^{*}$ basis set on top of B3LYP/6-31G* optimized structures (see Table 5.7). Hereafter, we use a short hand notation for such composite approaches where the // symbol is used to separate between the method for the single-point energy calculation and the method for the structure optimization. Thus, PBE0/DZVP//PBE/DZVP denotes PBE0/DZVP single-point energy calculations employing the PBE/DZVP optimized structures. If the symbol is absent, single-point energy calculations and structure optimizations are performed at the same level of theory.

To relate the results of Table 5.7 with previously reported theoretical results we list in Table 5.8 representative literature data for the $\mathrm{C}_{80}$ fullerene cages. As the first two columns of Table 5.7 show, increasing the basis set quality, i.e. from DZVP to TZVP, has almost no effect on the relative stability ordering and the relative energies. We can compare these PBE results directly with those published by Furche et al. [298], column 1 of Table 5.8. Here the seven $\mathrm{C}_{80}$ IPR isomers were optimized with the BP86/SVP and then single point energy calculations were performed at the BP86/TZVP level of theory. The $\mathrm{D}_{5 \mathrm{~d}}-1$ isomer was also found as ground state in this study (see Table 5.8). However, the ordering for the higher energy isomers differs significantly from our PBE/DZVP and PBE/TZVP ordering. We attribute this to the small basis set used in [298] for the structure optimization.

The used hybrid functionals have a significant effect on the relative energies as can be seen from the PBE0/DZVP//PBE/DZVP column of Table 5.7. With this methodology, the lowest-energy isomer is the $\mathrm{D}_{2}-2$, followed within less than $1 \mathrm{kcal} / \mathrm{mol}$ by the $\mathrm{D}_{5 \mathrm{~d}}-1$ isomer. A similar picture is obtained by Shao et al. [299] with the PBE0/6-311G*//DFTB methodology. However, the energy ordering of the $\mathrm{D}_{3}-4$ and $\mathrm{C}_{2 \mathrm{v}}-5$ isomers is reversed compared to ours. We attribute this to the semiempirical method used for structure optimizations in ref [299].

The B3LYP/6-31G* optimizations show a qualitative similar picture as the one obtained with the PBE0/DZVP//PBE/DZVP methodology. However, the energy separa-

### 5.2. EMPTY $\mathrm{C}_{80}$ FULLERENE CAGE

tion between the $D_{2}-2$ and $D_{5 d}-1$ isomers is more than doubled by the B3LYP/6-31G* method. Further B3LYP/6-311G* single point energy calculations on top of these B3LYP/6$31 G^{*}$ optimized structures reduce the energy difference between $D_{2}-2$ and $D_{5 d}-1$ (see the B3LYP/6-311G* //B3LYP/6-31G* column in Table 5.7) to a similar range as obtained with the PBE0/DZVP//PBE/DZVP composite approach. In order to analyze the PBE/DZVP, PBE/TZVP and B3LYP/6-31G* optimized structures, an alignment algorithm for molecular structures was employed [310]. The in this manner calculated similarity index is restricted to the interval $(0,1]$. It goes to zero if the two molecules are dramatically different in topology and becomes 1 if the molecules are equal. The obtained similarity indices of 0.998 for the PBE/DZVP vs PBE/TZVP and 0.997 for PBE/DZVP vs B3LYP/6-31G* optimized structures indicate almost perfect geometrical agreement between them. Thus our GGA optimized structures are almost indistinguishable from those optimized with hybrid functionals.

We can compare our B3LYP results with those summarized from the literature in Table 5.8, namely, B3LYP/6-31G* [300], B3LYP/6-31G*//B3LYP/6-31G and B3LYP/6-31+G*// B3LYP/6-31G [301]. In general, a similar picture is observed between these calculations. In particular, all B3LYP based methodologies predict the $\mathrm{D}_{2}-2$ as the lowest energy isomer. However, differences in the ordering of higher energy isomers, are observed. We attribute this, to the size of the basis set employed for the calculations in these references. Finally, the $\mathrm{D}_{2}-2$ ground state has also been confirmed by a MP2(FC)//B3LYP/6-31G* calculation [302].

In conclusion, using the ADFT PBE/DZVP/GEN-A2* methodology for fullerene optimizations and on top of these structures, PBE0/DZVP/GEN-A2* single-point energy calculations, yields results that are in agreement with those reported in the literature for hybrid functionals. However, our PBE0/DZVP//PBE/DZVP composite approach has the advantage over similar methods proposed in the literature [301, 302] that structure optimization is performed at the GGA rather than hybrid level of theory. As a result, our PBE0/DZVP//PBE/DZVP composite approach can be used to screen much larger number of systems of larger fullerenes without jeopardizing reliability.

Taking into account, that the stability of EMFs often follows the energetic trends of
anionic fullerenes, we also studied the corresponding di-, tetra- and hexa-anions of the $\mathrm{C}_{80}$ IPR fullerene cages. As Table 5.9 shows, both PBE/DZVP and PBE0/DZVP// PBE/DZVP methodologies give similar results. The most stable dianionic isomer is different from that of its tetra- and hexa-anion counterpart, likewise, these also differ from the neutral isomer found as minimum. Note the qualitative similarity to our $\mathrm{C}_{78}$ example in Figure 4.4. For the dianionic $\mathrm{C}_{80}$ fullerene cages, the $\mathrm{D}_{5 \mathrm{~h}}-6$ isomer is the most stable one, while for the tetra- and hexaanionic, the $\mathrm{I}_{\mathrm{h}}-7$ isomer is lowest in energy. Following the arguments from the literature, the most promising cage to encapsulate the uranium dimer is therefore, the $\mathrm{I}_{\mathrm{h}}-7$ isomer.

### 5.3 Structure Elucidation of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ System

After the validation of the electronic structure methodology for the $\mathrm{U}_{2}$ and $\mathrm{C}_{80}$ calculations, we performed a study of the $U_{2} @ C_{80}$ in order to determine the lowest-energy structure of this system. To this end, we enclosed the $\mathrm{U}_{2}$ in all optimized IPR isomers of the $\mathrm{C}_{80}$ fullerene. The uranium dimer was introduced into the fullerenes cages and these starting structures were locally optimized on the corresponding singlet, triplet, quintet, septet and nonet potential energy surfaces, respectively. From these calculations the septet formed by the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ IPR isomer was found as ground state. With the obtained septet $\mathrm{U}_{2} @ \mathrm{C}_{80}$ structure, a mass-scaled BOMD simulation was performed at 1200 K , in order to explore different orientations of the uranium dimer inside the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ cage. From the mass-scaled BOMD simulation, twenty well separated minima along the trajectory were selected as initial structures for further local

### 5.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} @ \mathrm{C}_{80}$ SYSTEM

Table 5.10: Relative ADFT energies and U-U distances ( $\mathrm{r}_{e}$ ) of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$, derived from the IPR $\mathrm{C}_{80}(7)$ cage. These data were obtained employing QECP pseudopotentials and corresponding valence basis sets for the uranium, whereas for carbon the DZVP all electron basis set was used.

optimizations.
Table 5.10 lists the relative energies of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system with septet multiplicity. Regardless of the initial structure taken from the mass-scaled BOMD trajectory, the two U atoms optimize to equivalent binding sites at opposite sides of the fullerene cage. The ${ }^{7} \mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ optimized structure found as the lowest energy structure ( $S_{1}$ in Figure 5.1) place the uranium atoms at the center of two six-membered rings on opposite sides of the cage. The U-U distance is $3.93 \AA$ and the closest U-C bond length is $2.50 \AA$ with an overall $D_{2 h}$ molecular symmetry. Only $0.08 \mathrm{kcal} / \mathrm{mol}$ above the lowest energy isomer, we found a second structure ( $\mathrm{S}_{2}$ in Figure 5.1), where the uranium atoms are located on-top of a carbon atom which connects three hexagons, with U-U distance of $3.91 \AA$ and the closest U-C bond lengths are $2.38,2.46$ and $2.49 \AA$ with an overall $\mathrm{C}_{\mathrm{i}}$ molecular symmetry. Also we found a third structure ( $\mathrm{S}_{3}$ in Figure 5.1) $0.49 \mathrm{kcal} / \mathrm{mol}$ higher in energy, with a $\mathrm{U}-\mathrm{U}$ distance of $3.91 \AA$. In this structure the uranium atoms are slightly off the $\mathrm{C}_{2}$ axis, which pass through the center of the hexagon-hexagon [6-6] bond in a $\mathrm{C}_{2 \mathrm{~h}}$ symmetry. Due to this deviation of the U positions from the $\mathrm{C}_{2}$ axis, the structure $\mathrm{S}_{3}$ has an overall $\mathrm{C}_{1}$ molecular symmetry.

Vibrational frequency calculations were carried out in order to verify the nature of these stationary points on the potential energy surface. We found only for the $S_{3}$ structure one imaginary frequency mode with an absolute value of $53 \mathrm{~cm}^{-1}$. This imaginary frequency means that the location of U ions in the $\mathrm{S}_{3}$ configuration is not stable and it is characterized as a transition state. The small energy spacing between the optimized structures, indicate the presence of a flat minimum on the potential energy surface of the $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ system

Figure 5.1: Representations of the $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ optimized structures listed in Table 5.10.
with regard to U movement along the cage wall.
PBE reoptimizations including an empirical dispersion energy term (PBE +D$)$ [311] were performed in order to analyze the effect of van der Waals interactions on the energies and bond distances of the two minima structures. Table 5.10 shows the results from these calculations using dispersion correction. Comparing the obtained results, we notice that the dispersion corrections do not change the results of relative energies and $\mathrm{U}-\mathrm{U}$ distances. However, PBE0 changes the relative energy ordering. Different to the results obtained with the PBE functional, not only the assignment of the ground state changes, also a larger energy separation between the $S_{1}$ and $S_{2}$ structures is observed.

An experimental and theoretical characterization of this dimetallic actinide EMF was published very recently by Zhang et al. [25]. In this study the structure of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ was characterized by means of single crystal diffraction (XRD). The crystal structure analysis shows that the endohedral $\mathrm{U}_{2}$ cluster is highly disordered inside the fullerene cage. From the XRD analysis, four model structures according to the $\mathrm{U}_{2}$ major occupancy were considered. It is reported that in these models, metal positions are not very different from each other, the uranium atoms are under hexagon faces, being close to or slightly off a $\mathrm{C}_{2}$ axis of the cage, with a U-U distance of 3.72 or $3.75 \AA$. Being the most predominant position the one where the uranium atoms are at the center of hexagon faces. Comparing this result with our minima structures, we found that the uranium positions inside the $\mathrm{C}_{80}$ fullerene coincide with those reported in Zhang's publication [25]. In the theoretical part of [25], density functional ge-

### 5.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} @ \mathrm{C}_{80}$ SYSTEM

ometry optimizations of these four model structures were carried out and a septet spin state was found with the lowest energy. Three symmetry equivalent structures, two with U-U distance of $3.74 \AA$ and one with $3.79 \AA$, where found with lowest energies. The fourth optimized structure, where the U-U distance $(3.72 \AA)$ matches the experimental one, is found 1.6 $\mathrm{kcal} / \mathrm{mol}$ above the other three. At this point it is important to note that these calculations were performed with the ADF program [312]. Thus, instead of using a relativistic corrected effective core potential the ZORA formalism [313] was used to incorporate scalar relativistic corrections into the calculation. Therefore, it is likely that the differences in the optimized U-U bond distances between [25] and our work are due to the different parametrizations for the treatment of scalar relativistic corrections. This is further supported by other theoretical results from [25] where the same QECP as in this work are used. These calculations yield practically the same optimized U-U bond lengths in $\mathrm{U}_{2} @ \mathrm{C}_{80}$ as reported here. Moreover, a second theoretical work published in 2015 by Foroutan-Nejad et al. [24], using a DFT program that also employed Stuttgart-Dresden effective core potentials predicted a septet ground state for this EMF system with a U-U bond distance of $3.89 \AA$ and an overall $\mathrm{C}_{\mathrm{i}}$ molecular symmetry, in good qualitative agreement with our results.

The U-U distances of 3.93 and $3.91 \AA$ obtained in the $\mathrm{S}_{1}$ and $\mathrm{S}_{2}$ isomers, respectively, are longer than twice the empirical single bond radius of uranium $(2 \times 1.7 \AA=3.4 \AA)$ [314], which suggests that the U-U bond order is lower than one. The nearest U-C bond lengths in $S_{1}$ and $S_{2}$ are in the range of 2.38-2.50 $\AA$, which are shorter than the summation of the van der Waals radius of the C atom and the ionic radius of $\mathrm{U}^{3+}(1.70 \AA+1.025 \AA=2.725$ $\AA$ ). This suggests that the interactions between $U$ and $C$ is not only electrostatic but also covalent.

To elucidate why the six-coordinated binding sites are the most stable places to locate the U ions, we calculated Mulliken charges and valences of the optimized empty $\mathrm{C}_{80}$ cage and of the $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ EMF in order to analyze the effects that the encapsulation of the two uranium atom causes on the electronic structure of the cage. Figure 5.2 depicts the charge difference on each carbon atom, as well as the C-C bond valence difference, between the empty cage and the cage with the two positive charged U atoms located at equivalent

Figure 5.2: Differences in carbon atom charges and C-C bond valences between the optimized empty $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ cage and the one with the uranium atoms enclosed. Blue represents gain in either charge or bond valences while red represents loss. The size of the circles and the thickness of the lines are proportional to this gain or loss.
binding sites at opposite sides of the cage analog to the $S_{1}$ and $S_{2}$ minima. Inspection of these figures reveals that regardless of the binding sites of the uranium atoms inside the cage, the charge transfer is mainly localized over the carbon atoms where the uranium is coordinated. A similar picture is observed for the C-C bond changes that are more or less localized over the cage regions where the uranium atoms are coordinated. Nevertheless, the losing and gaining of valence in the C-C bond is observed throughout the cage, regardless of the uranium coordination site in structures $S_{1}$ and $S_{2}$.

In Figure 5.3 the normalized number of bonds for the $\mathrm{S}_{1}, \mathrm{~S}_{2}$ and the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ empty cage are plotted versus the bond length. As this figure shows, a discrete distribution of bond lengths is found for the $S_{1}$ minimum, whereas for the $S_{2}$ minimum, a wide, in some ranges

### 5.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} @ \mathrm{C}_{80}$ SYSTEM

almost continuous, bond length distribution is observed. This indicates a more distorted $\mathrm{C}_{80}$ structure in the $S_{2}$ minimum. A pronounced difference between the $S_{1}$ and $S_{2}$ bond lengths distribution to the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ one is the appearance of four and nineteen elongated C-C bonds around $1.48 \AA$ and $1.47 \AA$ in $S_{1}$ and $S_{2}$, respectively. Whereas in $S_{1}$ a single elongated C-C bond length is found a group of lengthened C-C bond lengths can be observed from Figure 5.3 for $\mathrm{S}_{2}$. In both systems these elongated C-C bond lengths correspond to uranium coordination sites. Note the agreement with Figure 5.2 where the thick red lines indicate reduced C-C bond valency just at these coordination sites. Therefore, the charge transfer from uranium to the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ enhances locally the electron density of the carbon atoms at the coordination sites (blue circles in Figure 5.2) which in turn elongates the corresponding C-C bonds due to electrostatic repulsion. This manifests itself in a reduced bond valency of the corresponding C-C bonds. Thus, our analysis shows that charge transfer from $U_{2}$ to the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ cage is in both EMFs, $\mathrm{S}_{1}$ and $\mathrm{S}_{2}$, localized.

To validate these results, we also performed other population analyses. These analyses show that the uranium atoms possess positive charges in the $S_{1}$ and $S_{2}$ structures of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF system, $0.4 \mathrm{e}^{-}$for Mulliken, $0.5 \mathrm{e}^{-}$for Hirshfeld and $1.07 \mathrm{e}^{-}$in the natural bond order (NBO) population analysis. From the inspection of the bond order matrix values of the atoms in the $S_{1}$ and $S_{2}$ structures, specifically the values obtained between the uranium atoms and carbon atoms of the fullerene cage at which the uranium are located, we observed small values (0.39-0.56), indicating that the atoms in question participate in weak covalent bonding.

The simulated IR and Raman spectra for both minimum structures, $S_{1}$ and $S_{2}$, are depicted in Figure 5.4. First inspection by symmetry immediately reveals that the empty $\mathrm{C}_{80}$ fullerene isomer with $\mathrm{I}_{\mathrm{h}}$ symmetry has 62 normal modes from which 6 are IR and 14 are Raman active [29, 315, 316]. Both calculated spectra, IR and Raman, show many more peaks than those for the $\mathrm{I}_{\mathrm{h}}$-symmetric cage, indicating a symmetry reduction induced by the encapsulated U ions. Furthermore, in the low frequency range, below $200 \mathrm{~cm}^{-1}$, the metaldependent modes appear, whereas peaks above $200 \mathrm{~cm}^{-1}$ can be assigned to cage vibrational modes.

Figure 5.3: Bond lengths distribution. Dashed lines represent the two different C-C bonds in a perfect artificial icosahedral $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ empty cage while dotted lines are the same but for the hexaanionic one. Both, dashed and dotted black lines, correspond to a $[6,6]$ bond (a bond shared between two hexagons) and magenta lines to a [6,5] bond (a bond shared between a hexagon and a pentagon).

In a more detailed inspection of the low frequency range, we found six vibrational features of the encapsulated $U_{2}$ unit, three of them are IR active whereas the remaining three are Raman active. The peaks observed at 39, 49 and $145 \mathrm{~cm}^{-1}$ for structure $\mathrm{S}_{1}$ and at 25,37 and $140 \mathrm{~cm}^{-1}$ for structure $\mathrm{S}_{2}$ in the IR spectrum of the Figure 5.4, are uranium based modes due to the frustration of $U_{2}$ translations, which are transformed into $U_{2}$ vibrations inside the $\mathrm{C}_{80}$

### 5.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} @ \mathrm{C}_{80}$ SYSTEM

cage. However, these translational-like IR-active modes are so weak in intensity that they are barely visible. For this reason, these weak modes are depicted in the inset of the IR spectra of Figure 5.4. In the Raman spectra, a degenerated peak observed at $52 \mathrm{~cm}^{-1}$ for structure $S_{1}$ and two peaks at 18 and $30 \mathrm{~cm}^{-1}$ for structure $S_{2}$ are also uranium based modes. They are due to the frustration of the $\mathrm{U}_{2}$ rotation inside the $\mathrm{C}_{80}$ cage. These observable frustrated $\mathrm{U}_{2}$ translational and rotational modes can be taken as a direct evidence for the encapsulation of $\mathrm{U}_{2}$ and the formation of $\mathrm{U}_{2}-\mathrm{C}_{80}$ bonds. The remaining Raman active peak at $120 \mathrm{~cm}^{-1}$ for structure $S_{1}$ and at $107 \mathrm{~cm}^{-1}$ for structure $S_{2}$ are assigned to the combination of the $\mathrm{U}-\mathrm{U}$ stretching mode with the vibrational mode elongating the fullerene cage along the $\mathrm{U}-\mathrm{U}$ axis. It can be interpreted as a stretching metal-cage vibration. Some publications [317-319] suggest that this Raman peak since it is also observed in the same wavenumber region in other EMFs, and originates from the motion of the encapsulated metal ions in the carbon cages, can be taken as a fingerprint vibration for EMFs.

The Raman spectra peaks in the range of $200-250 \mathrm{~cm}^{-1}$ in both structures, $S_{1}$ and $S_{2}$, can be assigned to breathing modes of the $\mathrm{C}_{80}$ cage. Note that in the recently published experimental [25] low energy Raman spectrum of the $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ system, three major peaks are observed, one at $121 \mathrm{~cm}^{-1}$ assigned as metal-to-cage vibration mode, and two peaks at 218 and $234 \mathrm{~cm}^{-1}$ assigned to cage vibrational modes. Thus, our computations are able to reproduce these major peaks of the experimental spectrum.

In our ADFT calculations four intense IR bands (493, 624, 1179 and $1370 \mathrm{~cm}^{-1}$ ), as shown in Figure 5.5, are found for the $\mathrm{C}_{80}^{6-}-\mathrm{I}_{\mathrm{h}}(7)$ cage. This is in agreement with another DFT-computed spectra [320] for this system. The strong cage mode at 493 and at $1370 \mathrm{~cm}^{-1}$ can be related to the IR bands of $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ at 500 and $1400 \mathrm{~cm}^{-1}$, respectively for both structures, whereas the other two intense cage modes at 624 and $1179 \mathrm{~cm}^{-1}$ have no clear counterparts in the spectrum of $\mathrm{U}_{2} @ \mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ as Figure 5.5 shows.

Figure 5.4: Simulated IR (top) and Raman (bottom) spectra for $U_{2} @ C_{80}$ structures $S_{1}$ and $S_{2}$ (inset: IR spectrum from $0-160 \mathrm{~cm}^{-1}$ ).

### 5.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} @ \mathrm{C}_{80}$ SYSTEM

Figure 5.5: ADFT-computed IR spectra of structures $S_{1}$ and $S_{2}$ of the $U_{2} @ C_{80}$ system compared to the empty $\mathrm{C}_{80}^{6-}$ cage.

In conclusion, our ADFT studies of $U_{2} @ C_{80}$ EMF system yield a $D_{2 h}$ ground state with septet spin multiplicity. This is in accordance with experimental evidence, where an isomer very closed to $\mathrm{D}_{2 \mathrm{~h}}$ symmetry was reported to be lowest in energy, recently [25]. Our two minimum structures together with the transition state structure are very closed in energy, indicating a flat potential energy surface of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ system. It suggests an almost free movement from one configuration to another, in good agreement with the disorder of the U atoms observed crystallographically [25]. The electronic structure analysis for the most stable $\mathrm{D}_{2 \mathrm{~h}}$ configuration reveals that the charge transfer from the U atoms to the cage as well as the changes in the C-C bond strengths are localized over the cage regions where the uranium atoms are coordinated. The simulated Raman spectra are able to reproduce the most important features of the experimental spectrum (which is reported in a low-energy
range, from 100 to $600 \mathrm{~cm}^{-1}$ ) in the range between 120 and $230 \mathrm{~cm}^{-1}$. Structure $S_{1}$ and $S_{2}$ show a low frequency peak at 120 and $107 \mathrm{~cm}^{-1}$, respectively, corresponding to a stretching metal-cage vibration, that appears at $121 \mathrm{~cm}^{-1}$ in the experimental spectrum. The peak observed between 208 and $223 \mathrm{~cm}^{-1}$ in the simulated spectra assigned to breathing modes of the cage, appear to be shifted by around $11 \mathrm{~cm}^{-1}$ to lower frequencies when compared to those reported experimentally [25].

## Chapter 6

## Structure Determination of $\mathrm{U}_{2} \mathrm{C}_{79}$

Isolation and characterization of endohedral fullerenes suffers from extraordinary low synthetic yields and difficult purification processes. In this respect, the recently produced $\mathrm{U}_{2} \mathrm{C}_{79}$ system by the research group of Dr. Echegoyen [26, 27], is no exception. So far the pure compound has not been isolated in order to characterize its properties. Thus, only its exact mass is known from mass spectrometry. For this reason, theoretical methods to obtain insights into the geometrical and electronic structure of $\mathrm{U}_{2} \mathrm{C}_{79}$, were employed.

Since fullerene cages can only be built from an even numbers of carbon atoms, it is reasonable to assume that one or more carbon atoms in $\mathrm{U}_{2} \mathrm{C}_{79}$ is/are found inside the host cage, likely in the form of a metallic carbide. Thus, the question arises; is $\mathrm{U}_{2} \mathrm{C}_{79}$ a $\mathrm{U}_{2} \mathrm{CC}_{78}$ or a $\mathrm{U}_{2} \mathrm{C}_{3} \mathrm{C}_{76}$ ? To this end, we have performed ADFT calculations of $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ and $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ as possible structure motifs for the experimentally observed $\mathrm{U}_{2} \mathrm{C}_{79}$ system.

### 6.1 Free Clusters: $\mathrm{U}_{2} \mathrm{C}$ and $\mathrm{U}_{2} \mathrm{C}_{3}$

Following our working strategy, we begin with the study of the $\mathrm{U}_{2} \mathrm{C}$ and $\mathrm{U}_{2} \mathrm{C}_{3}$ clusters. The optimizations of $\mathrm{U}_{2} \mathrm{C}$, starting from $\mathrm{C}_{2 \mathrm{v}}, \mathrm{D}_{\infty \mathrm{h}}$ and $\mathrm{C}_{\infty \mathrm{v}}$ structures, whereas for the $\mathrm{U}_{2} \mathrm{C}_{3}$, starting from $\mathrm{D}_{3 \mathrm{~h}}, \mathrm{C}_{2 \mathrm{v}}$ and $\mathrm{C}_{1}$ structures, were performed with different spin multiplicities. The motifs of these starting structures are depicted in Figure 6.1.

Figure 6.1: Motifs of the $C_{2 v}$ (a), $D_{\infty h}$ (b) and $C_{\infty v}$ (c) structures for the $U_{2} C$ cluster and $D_{3 h}$ $(d), C_{2 v}(e$ and $f)$ and $C_{1}(g)$ structures for the $U_{2} C_{3}$ cluster.

Table 6.1 lists the relative energies of the $\mathrm{U}_{2} \mathrm{C}$ optimized structures with different spin multiplicities along with their structure parameters. As this Table shows the $\mathrm{U}_{2} \mathrm{C}$ ground state is a $\mathrm{C}_{2 \mathrm{v}}$ septet with optimized U-C and U-U bond lengths of $2.06 \AA$ and $2.84 \AA$, respectively. Note that the most stable $\mathrm{U}_{2} \mathrm{C}$ septet possesses the longest $\mathrm{U}-\mathrm{U}$ bond among all the $\mathrm{C}_{2 \mathrm{v}}$ symmetry structures, indicating that the bonding between the two uranium atoms in $\mathrm{U}_{2} \mathrm{C}$ is weak. Moreover, the uranium atoms are positively charged, $+0.59 \mathrm{e}^{-}$according to the iterative Hirshfeld population analysis, which results in an electrostatic repulsion between them. Thus, the optimized $\mathrm{C}_{2 \mathrm{v}}$ structure for the septet ground state is the best compromise between the attractive and repulsive interactions between the two uranium atoms and the electron distribution at the carbon atom.

### 6.1. FREE CLUSTERS: $\mathrm{U}_{2} \mathrm{C}$ AND $\mathrm{U}_{2} \mathrm{C}_{3}$

Table 6.1: Relative ADFT energies and structure parameters for optimized $\mathrm{U}_{2} \mathrm{C}$ clusters. See Figure 6.1 for cluster structures and atom labeling.

| 9 | 49.80 | 4.44 | 1.90 | 2.54 | - | 180.0 |

In Table 6.2 the relative energies and optimized structure parameters of the $\mathrm{U}_{2} \mathrm{C}_{3}$ cluster with different spin multiplicities are listed. As this Table shows the $\mathrm{U}_{2} \mathrm{C}_{3}$ ground state is also a septet structure. Although the optimization of this structure started from an initial $\mathrm{C}_{2 \mathrm{v}}$ symmetry it optimized to a $\mathrm{C}_{1}$ structure (see Figure 6.2 ). The U-C bond lengths with the individual carbon atom $\left(\mathrm{U}-\mathrm{C}_{3}\right)$ is in the same range as in the $\mathrm{U}_{2} \mathrm{C}$ ground state, but the U-C bonds to the $\mathrm{C}_{2}$ unit ( $\mathrm{U}_{1}-\mathrm{C}_{1}$ and $\mathrm{U}_{2}-\mathrm{C}_{2}$ ) are considerably longer with a value of $2.25 \AA$.

Figure 6.2: The lowest energy $\mathrm{U}_{2} \mathrm{C}_{3}$ optimized structure with septet spin multiplicity.

Table 6.2: Relative ADFT energies and structure parameters for $\mathrm{U}_{2} \mathrm{C}_{3}$ clusters. See Figure 6.1 and 6.2 for cluster structures and atom labeling, for the lowest-energy structure.

### 6.2 Empty Cages: $\mathrm{C}_{76}$ and $\mathrm{C}_{78}$

For this study we considered IPR as well as non-IPR cages for the $\mathrm{C}_{76}$ and $\mathrm{C}_{78}$ fullerene cages. Structurally, there are a total of 19151 and 24109 isomers of the $\mathrm{C}_{76}$ and $\mathrm{C}_{78}$ fullerene cages, respectively. Of these, only 2 are IPR isomers for the $\mathrm{C}_{76}$ fullerene, while for the $\mathrm{C}_{78}$ 5 isomers satisfy the IPR. In order to select a set of non-IPR cages, we took into account that, in general, the number of adjacent pentagon pairs present in EMF based on non-IPR isomers, is equal to the number of metal ions in the endohedral cluster. For this reason, we selected all possible $\mathrm{C}_{76}$ and $\mathrm{C}_{78}$ fullerenes cages that contain two adjacent pentalene pairs (APP). Thus, we considered altogether 11 non-IPR isomers of the $\mathrm{C}_{76}$ and 228 of the $\mathrm{C}_{78}$

### 6.2. EMPTY CAGES: $\mathrm{C}_{76}$ AND $\mathrm{C}_{78}$

fullerene cage.
To this end, we optimized the neutral cages of $\mathrm{C}_{78}$ and $\mathrm{C}_{76}$ as well as their charged hexaanions employing the $\mathrm{PBE} / \mathrm{DZVP} / \mathrm{GEN}-\mathrm{A} 2 *$ methodology. The relative ADFT energies (in $\mathrm{kcal} / \mathrm{mol}$ ) for these optimized fullerene cages are listed in Table 6.3. Results for the most stable species are given in bold. We found that the most stable neutral isomer of the $\mathrm{C}_{76}$ possess a $D_{2}$ cage symmetry. This is in agreement with the reported data by Kikuchi et al. [321] and Diederich et al. [322] who isolated, characterized and identified the fullerene $\mathrm{C}_{76}\left(\mathrm{D}_{2}-19150\right)$ among others cages.

From the five-possible neutral IPR isomers of $\mathrm{C}_{78}$, we found the $\mathrm{C}_{2 \mathrm{v}}-24107$ isomer as the most stable structure. This result is also in agreement with the reported data by Diederich et al. [323] and Nakahara et al. [324] who isolated and elucidated the structure of the $\mathrm{C}_{78}$ by ${ }^{13} \mathrm{C}$ NMR spectroscopy. Our results are also in agreement with other theoretical DFT studies for these neutral fullerene cages [325-327].

Table 6.3: Relative ADFT energies ( $\Delta \mathrm{E}$, in $[\mathrm{kcal} / \mathrm{mol}]$ ) for the neutral and hexaanionic empty cages of the $\mathrm{C}_{76}$ and $\mathrm{C}_{78}$ fullerenes. APP is the number of adjacent pentalene pairs present in each fullerene isomer.

| Fullerene | APP | $\mathrm{C}_{76}$ | $\mathrm{C}_{76}^{6-}$ | Fullerene | APP | $\mathrm{C}_{78}$ | $\mathrm{C}_{78}^{6-}$ |
| :--- | :---: | ---: | ---: | :--- | :---: | :---: | :---: |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-17465\right)$ | 2 | 42.71 | 16.70 | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-21975\right)$ | 2 | 51.80 | 29.10 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{\mathrm{s}}-17490\right)$ | 2 | 51.60 | $\mathbf{0 . 0 0}$ | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-21981\right)$ | 2 | 63.51 | 30.85 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-17491\right)$ | 2 | 59.10 | 22.01 | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-21982\right)$ | 2 | 58.60 | 35.50 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-17508\right)$ | 2 | 48.00 | 35.70 | $\mathrm{C}_{78}\left(\mathrm{C}_{2}-22010\right)$ | 2 | 59.04 | 14.85 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{2}-17512\right)$ | 2 | 58.54 | 14.50 | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-22135\right)$ | 2 | 59.81 | 35.64 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-17588\right)$ | 2 | 44.30 | 18.70 | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-22646\right)$ | 2 | 48.40 | 26.90 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-17760\right)$ | 2 | 40.61 | 19.14 | $\mathrm{C}_{78}\left(\mathrm{C}_{1}-23298\right)$ | 2 | 45.00 | 39.40 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{2}-17765\right)$ | 2 | 55.60 | 13.30 | $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24088\right)$ | 2 | 55.04 | 28.15 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{2}-18161\right)$ | 2 | 49.45 | 15.60 | $\mathrm{C}_{78}\left(\mathrm{D}_{3}-24105\right)$ | 0 | 10.72 | 47.01 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{1}-18943\right)$ | 2 | 38.03 | 42.65 | $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24106\right)$ | 0 | 7.80 | 55.91 |
| $\mathrm{C}_{76}\left(\mathrm{C}_{2}-18944\right)$ | 2 | 34.20 | 33.70 | $\mathrm{C}_{78}\left(\mathrm{C}_{2 \mathrm{v}}-24107\right)$ | 0 | $\mathbf{0 . 0 0}$ | 23.40 |
| $\mathrm{C}_{76}\left(\mathrm{D}_{2}-19150\right)$ | 0 | $\mathbf{0 . 0 0}$ | 24.50 | $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24108\right)$ | 0 | 25.85 | 79.20 |
| $\mathrm{C}_{76}\left(\mathrm{~T}_{\mathrm{d}}-19151\right)$ | 0 | 10.00 | 4.70 | $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ | 0 | 2.31 | $\mathbf{0 . 0 0}$ |

From the relative stabilities of the $\mathrm{C}_{76}$ hexaanions (see Table 6.3), it follows that a non-IPR isomer, namely $\mathrm{C}_{\mathrm{s}}-17490$, is the ground state. For the $\mathrm{C}_{78}$ hexaanions we found that the $\mathrm{D}_{3 \mathrm{~h}}{ }^{-}$ 24109 IPR isomer is most stable. Thus, in both fullerenes the most stable hexaanionic isomer
is different from that of its neutral counterpart. Following arguments from the literature, the most promising cages are therefore $\mathrm{C}_{76}\left(\mathrm{C}_{\mathrm{s}}-17490\right)$ and $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ for $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ and $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$, respectively.

### 6.3 Structure Elucidation of the $\mathrm{U}_{2} \mathrm{C}_{79}$ System

 structures, in order to elucidate the spin multiplicity of the lowest-energy structure. With these structure mass-scaled BOMD simulations will be performed in a following step. For these local optimizations, we enclosed the $\mathrm{U}_{2} \mathrm{C}$ and $\mathrm{U}_{2} \mathrm{C}_{3}$ minima structures in the $\mathrm{D}_{3 \mathrm{~h}^{-}}$ 24109, $\mathrm{C}_{2}-22010$ and $\mathrm{C}_{2 \mathrm{v}}-24107$ isomers of the $\mathrm{C}_{78}$ and in the $\mathrm{C}_{\mathrm{s}}-17490$ and $\mathrm{T}_{\mathrm{d}}-19151$ isomers of the $\mathrm{C}_{76}$ fullerene cage, respectively. The resulting endohedral fullerenes structures were optimized on the corresponding singlet, triplet, quintet, septet and nonet potential energy surfaces.

Table 6.4 lists the relative energies from the local optimizations of the $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}}$ system. As Table 6.4 shows, we find as lowest-energy structure the EMF with the $\mathrm{U}_{2} \mathrm{C}$ cluster inside the $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ IPR isomer with a triplet spin multiplicity. For this endometallofullerene, the $\mathrm{U}_{2} \mathrm{C}$ cluster is sandwiched between two six-membered rings, as shown in Figure 6.3-a, resulting in an overall $\mathrm{D}_{3 \mathrm{~h}}$ symmetry. The two closest structures in energy ( $<20 \mathrm{kcal} / \mathrm{mol}$ ) to this one are the systems formed by the same $\mathrm{C}_{78}$ IPR isomer, $\mathrm{D}_{3 \mathrm{~h}}-24109$, but with singlet and quintet spin multiplicities. In all these structures the $\mathrm{U}_{2} \mathrm{C}$ unit is linear and oriented along the $\mathrm{C}_{3}$ axis.

Table 6.5 lists the relative energies for the $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ system. The lowest-energy $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ structure consists of a $\mathrm{C}_{2 \mathrm{v}} \mathrm{U}_{2} \mathrm{C}_{3}$ cluster encapsulated into the $\mathrm{T}_{\mathrm{d}}-19151$ fullerene isomer in triplet spin multiplicity. In this structure, the uranium atoms of the $\mathrm{U}_{2} \mathrm{C}_{3}$ cluster are coordinated to hexagons on opposite sides of the cage, as depicted in Figure 6.3-b. The overall symmetry is $\mathrm{C}_{2 \mathrm{v}}$ for the found $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ minimum structure with triplet spin multiplicity. As this Table shows, the $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ EMF structures are all much higher in energy as the $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ structures (see the $\Delta \mathrm{E}_{\mathrm{C}_{78}}$ column). Due to this energy difference of the $\mathrm{U}_{2} \mathrm{C}_{79}$ sys-

### 6.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} \mathrm{C}_{79}$ SYSTEM

Table 6.4: Relative ADFT energies for the $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ endohedral fullerenes.

${ }^{a}$ Relative energies of the $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ isomers with respect to the lowest-energy ${ }^{3} \mathrm{U}_{2} \mathrm{C}^{\mathrm{C}} \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ structure.

Based on Table 6.4 and 6.5 we selected the $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ triplet minimum as starting structure for the mass-scaled BOMD simulation in order to explore different positions and arrangements of the $\mathrm{U}_{2} \mathrm{C}$ cluster inside the $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ fullerene isomer. The massscaled BOMD simulation was performed at 1600 K , a higher temperature than the one used for the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF system (1200 K). This was due to the fact that after 5000 fs very few conformational changes were observed throughout the molecular dynamics trajectory hence, it was decided to raise the simulation temperature, with the aim of promoting structural rearrangements.

Figure 6.3: Optimized structures for ${ }^{3} \mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}$ (24109) (a) and ${ }^{3} \mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ (19151) (b) endohedral fullerenes. Endohedral carbon atoms are represented in cyan, whereas the uranium atoms are in yellow.

From the mass-scaled BOMD simulation, twenty structures were taken as starting points for local optimizations. These calculations were performed with singlet, triplet, quintet and septet spin multiplicity. In Table 6.6 the relative energies and optimized structure parameters of the $\mathrm{U}_{2} \mathrm{C}$ cluster inside the $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ isomer with different spin multiplicities, are listed. As this Table shows, the ground state is the structure with triplet spin multiplicity, with optimized U-U and U-C bond lengths of 4.09 and $2.04 \AA$, respectively, and with a U-C-U angle of $180.0^{\circ}$.

Table 6.6: Relative ADFT energies for the $\mathrm{U}_{2} \mathrm{C}_{79}$ endohedral fullerene, formed by the $\mathrm{U}_{2} \mathrm{C}$ cluster inside the $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ fullerene isomer with different spin multiplicities.

| Multiplicity | $\Delta \mathrm{E}$ <br> $[\mathrm{kcal} / \mathrm{mol}]$ | $\mathrm{U}-\mathrm{U}$ <br> $[\AA]$ | $\mathrm{U}-\mathrm{C}$ <br> $[\AA]$ | $\mathrm{U}-\mathrm{C}-\mathrm{U}$ <br> $\left[{ }^{\circ}\right]$ |

| 7 | 37.30 | 4.21 | 2.10 | 179.8 |

### 6.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} \mathrm{C}_{79}$ SYSTEM

 for the $\mathrm{U}_{2} \mathrm{C}$ positive charges of 3.1 e on each uranium atom and a negative charge of -2.3 e on the central carbon atom. This analysis suggests that the linear $\mathrm{U}_{2} \mathrm{C}$ in this EMF is electrostatic dominated by the large repulsion between the two uranium atoms. Assuming that the $\mathrm{U}_{2} \mathrm{C}$ cluster donates around four electrons to the $\mathrm{C}_{78}$ cage, $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ can be considered to be $\left(\mathrm{U}_{2} \mathrm{C}\right)^{4+} @ \mathrm{C}_{78}{ }^{4-}$.

Recently, Ying et al. [21] published a theoretical study on a series of carbide clusterfullerenes (CCFs) of the form $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{2 n}}(2 n=60,68,72,78,80,88,96,104)$. Accordingly
 each uranium atom is situated over a bond shared by a pentagon and a hexagon [5,6], with an overall $\mathrm{C}_{2 \mathrm{v}}$ molecular symmetry. The electronic structure of this EMF is formally assigned as $\left(\mathrm{U}_{2} \mathrm{C}\right)^{6+} @ \mathrm{C}_{78}{ }^{6-}$ with U-C bond length of $2.01 \AA$ and U-C-U bond angle of $123.9^{\circ}$. These results were obtained by using the M06-2X functional with the $6-31 \mathrm{G}^{*}$ all-electron basis set for the carbon atoms and the Stuttgart-Dresden relativistic effective core potential and corresponding basis set for the uranium atoms [21]. In Ying's work, the $\mathrm{U}_{2} \mathrm{C}$ cluster shape could be due to the $[5,6]$ coordination site of the uranium atoms, over which the cluster donates six electrons to the cage, favouring a bent cluster shape. In contrast, in our work we found a linear $\mathrm{U}_{2} \mathrm{C}$ cluster with the metal ions coordinated over carbon six membered-rings. Furthermore, we assigned the electronic structure of this EMF to $\left(\mathrm{U}_{2} \mathrm{C}\right)^{4+} @ \mathrm{C}_{78}{ }^{4-}$ based on an iterative Hirshfeld population analysis. To investigate these differences between the work of Ying et al. and our work here we performed structure optimizations of the minimum reported by Ying et al. [21] with the here proposed methodology. This $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right) ~}_{\text {2 }}$ (20) optimized structure is shown in Figure 6.4 (top) and compared with our minimum structure (bottom). It has a U-C bond length of $2.04 \AA$ and a U-C-U bond angle of $123.7^{\circ}$. These results are in agreement with those reported by Ying et al. [21]. However, this structure is at the PBE level of theory $43.5 \mathrm{kcal} / \mathrm{mol}$ higher in energy than our previously reported minimum with a linear $\mathrm{U}_{2} \mathrm{C}$ unit (see Figure 6.4 (bottom)). To investigate the influence of the exchange-correlation functional choice on the energy separation we also performed single point energy calculations with PBE0, B3LYP and M06-2X hybrid functionals on top
of the PBE optimized structures depicted in Figure 6.4. In all cases, the here proposed $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ minimum structure with a linear $\mathrm{U}_{2} \mathrm{C}$ unit resulted to be the ground state. The energy differences with respect to the minimum structure proposed by Ying et al. [21] are $36.02,56.93$ and $16.15 \mathrm{kcal} / \mathrm{mol}$ at the PBE0, B3LYP and M06-2X level of theory, respectively. This confirms the existence of a linear $\mathrm{U}_{2} \mathrm{C}$ unit in the $\mathrm{U}_{2} \mathrm{C}^{\mathrm{C}} \mathrm{C}_{78}$ EMF. Finally, in order to compare the energies between broken-symmetry (BS) approximate solutions with the previously obtained UKS energy for the $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}}$ EMF system, we performed a single-point energy calculation, employing the obtained density from the UKS calculation as a starting density, in which the molecular orbital occupation was accordingly modified. Such modification consists in breaking the symmetry, by changing one spin alpha to a beta. The obtained relative energy of this BS calculation with respect to the UKS calculation is of $0.2 \mathrm{kcal} / \mathrm{mol}$. Due to the fact that the BS calculation was higher in energy with respect to our previously reported UKS minimum structure, no further investigation was made in this direction.

Figure 6.4: The $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ optimized structure starting from the reported minimum of [21] (top) and the most stable structure from this work (bottom) with triplet spin multiplicity. These structures were obtained employing the PBE/DZVP/GEN-A2* and the PBE/QECP/GENA2** methodologies for the carbon and uranium atoms, respectively.

### 6.3. STRUCTURE ELUCIDATION OF THE $\mathrm{U}_{2} \mathrm{C}_{79}$ SYSTEM

With the aim to gain more insight into the $\mathrm{U}_{2} \mathrm{C}_{79}$ system and to stimulate further experimental studies the infrared (IR) and Raman spectra were calculated. In Figure 6.5 the
 spin multiplicity are graphically displayed. Not metal-dependent modes are found in the lowwavenumber range (below $200 \mathrm{~cm}^{-1}$ ) of the calculated IR spectrum. Instead, the asymmetric U-C-U stretching mode combined with the vibrational mode elongating the fullerene cage along the U-C-U axis appears as a pronounced feature at $557 \mathrm{~cm}^{-1}$ indicated by a black dot in the upper spectrum of Figure 6.5. In addition, two major peaks at 492 and $1414 \mathrm{~cm}^{-1}$ assigned to cage vibrational modes, are observed in the IR spectrum. In the Raman spectrum five vibrational features of the encaged cluster are observed in the low frequency range. The first four peaks appears in a range between 0 to $100 \mathrm{~cm}^{-1}$ (see inset in the Raman spectrum of Figure 6.5). The peaks observed at 55 and $59 \mathrm{~cm}^{-1}$ (indicated in the Raman spectrum of Figure 6.5 with black dots) are frustrated UCU rotational modes. The next two peaks at 65 and $68 \mathrm{~cm}^{-1}$ (also indicated with black dot) are only weakly Raman active and are assigned to UCU bending modes.

Another Raman active peak at $177 \mathrm{~cm}^{-1}$ is assigned to the symmetric UCU stretching mode combined with the vibrational mode elongating the fullerene cage along the $\mathrm{U}-\mathrm{C}-\mathrm{U}$ axis. Again it can be interpreted as a stretching metal-cage vibration. Other peaks at 488 and $1404 \mathrm{~cm}^{-1}$ are characterized by strong intensity and can be assigned to cage vibrational modes.

In conclusion, our ADFT studies of the $\mathrm{U}_{2} \mathrm{C}_{78}$ and $\mathrm{U}_{2} \mathrm{C}_{3} @ \mathrm{C}_{76}$ EMF systems predict that $\mathrm{U}_{2} \mathrm{C}_{79}$ corresponds to the $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ EMF structure. The simulated IR and Raman spectra provide enough information in order to guide the experimental characterization of this structure in the future.

Figure 6.5: Simulated IR (top) and Raman (bottom) spectra of the $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right) \text { endo- }}^{\text {( }}$ hedral fullerene in triplet spin multiplicity. Observed UCU vibrations are indicated by black dots.

## Chapter 7

## Structure Determination of $\mathrm{Lu}_{3} \mathrm{C}_{107}$

Isolation and characterization of higher fullerenes are hampered due to their low abundance in fullerene soot and poor solubility in common solvents. In addition, higher fullerenes can exist as numerous isomers which make the identification of their structures challenging [328]. Thus, chemical modifications such as exohedral and endohedral additions have been applied to alter the electronic structure of higher and giant fullerenes with hundred and more carbon atoms to make them more soluble. So far, the largest cage unequivocally characterized in an EMF is $\mathrm{C}_{108}$ in $\mathrm{Y}_{2} \mathrm{C}_{2} @ \mathrm{C}_{108}\left(\mathrm{C}_{1}-1660\right)$ [329].

Recently, Sarina and coworkers [28] were able to detect by mass spectrometry several new families of endohedral fullerenes, specially the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ to $\mathrm{Lu}_{3} \mathrm{C}_{115}$ with odd number of carbon atoms. Here we perform ADFT studies to reveal the possible molecular structure of the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ species. Assuming that trapped lutetium clusters could include individual carbon atoms or a $\mathrm{C}_{3}$ unit, we have performed ADFT calculations of $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ and $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}$ as motifs for the experimental observed $\mathrm{Lu}_{3} \mathrm{C}_{107}$ specie.

### 7.1 Free Clusters: $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$

The study was initialized with the methodology validation for the lutetium dimer. The calculations were performed employing the ADFT approach. For the calculations of the exchangecorrelation energy and potential the PBE functional was used. The GGA optimized DZVP all
electron basis set was used for the carbon whereas for lutetium two quasi-relativistic, small(QECP43) and large-core (QECP11) pseudopotentials from the Stuttgart-Dresden library in combination with the corresponding valence basis sets [276], were employed. For the fitting of the density, the GEN-A2** auxiliary function set was used.

Table 7.1 lists the PBE/QECP43 and PBE/QECP11 results for the lutetium dimer with different spin multiplicities. As this Table shows, a triplet multiplicity ground state is obtained with both pseudopotentials. This result is in agreement with DFT calculations, reported by Qiong et al. [330], and with the coupled-cluster calculations (employing the core polarization potential (CPP) approach adapted for pseudopotentials), reported by Cao et al. [331] (see Table 7.1).

The calculated equilibrium bond lengths are listed in Table 7.1, too. With the QECP43 pseudopotential, the predicted bond length for the triplet ground state is smaller ( $3.07 \AA$ ) than the predicted one by the QECP11 pseudopotential (3.16 $\AA$ ). It can be noted that all bond lengths predicted with the QECP11 pseudopotential are longer than their respective counterparts calculated with the QECP43 pseudopotential (see Table 7.1). The same trend is observed in the calculations reported by Qiong et al. [330]. The vibrational frequency predicted by the $\mathrm{PBE} / \mathrm{QECP} 43$ of $118.2 \mathrm{~cm}^{-1}$ is comparable to the one from $\operatorname{CCSD}(\mathrm{T})$ calculations ( $120.0 \mathrm{~cm}^{-1}$ ) and in good agreement with the experimentally reported value of $121.6 \pm 0.8 \mathrm{~cm}^{-1}$ [332]. The QECP43 and QECP11 calculated dissociation energies for the $\mathrm{Lu}_{2}$ in the triplet ground state are comparable with the experimental value of 32.98 $\pm 7.84 \mathrm{kcal} / \mathrm{mol}$ [333] (see Table 7.1). Moreover, these PBE/QECP43 and PBE/QECP11 calculated dissociation energies are also in good agreement with the single point dissociation energies calculated with PBE0 on top of the PBE optimized lutetium dimer (see bold values in parentheses in Table 7.1). Furthermore all here calculated dissociation energies for the $\mathrm{Lu}_{2}$ are comparable with the obtained value from $\operatorname{CCSD}(\mathrm{T})$ calculations. By comparing with the available experimental and high-level ab-initio results, we decided to choose the QECP43 pseudopotential and its corresponding valence basis set for further calculations with the lutetium atom.

Having chosen the methodology for the theoretical study of the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ EMF system,

### 7.1. FREE CLUSTERS: $\mathrm{LU}_{3} \mathrm{C}$ AND $\mathrm{LU}_{3} \mathrm{C}_{3}$

Table 7.1: Relative energies $(\Delta \mathrm{E})$, equilibrium bond distances $\left(\mathrm{r}_{e}\right)$, dissociation energies $\left(\mathrm{D}_{e}\right)$ and harmonic vibrational frequencies $\left(\omega_{e}\right)$ for the lutetium dimer. Bold values in parentheses correspond to single point dissociation energies calculated with PBE0 on top of the PBE optimized dimer. In ref. [330] SSC: Stuttgart-Small-Core and SLC: Stuttgart-Large-Core.

we turn to the study of the free $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ clusters. To this end the free clusters were optimized with different spin multiplicities. The motifs of the $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ cluster minima are depicted in Figure 7.1. Table 7.2 lists the relative energies of the optimized minimum structures of $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ with different spin multiplicities along with their structure parameters. As this Table shows the ground state for $\mathrm{Lu}_{3} \mathrm{C}$ cluster is a doublet in $\mathrm{C}_{\mathrm{s}}$ symmetry. In this most stable structure, Lu atoms form a distorted trigonal pyramidal cluster with the carbon atom. The Lu-C bond lengths are of 2.11 and $2.10 \AA$, whereas the shorter sides of the triangle have $\mathrm{Lu}-\mathrm{Lu}$ distance of $3.30 \AA$. Note that the most stable $\mathrm{Lu}_{3} \mathrm{C}$ doublet possesses the longest $\mathrm{Lu}-\mathrm{Lu}$ distances.

Table 7.2: Relative energies $(\Delta \mathrm{E})$ and structures parameters for the $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ clusters. See Figure 7.1 for cluster structures and atom labeling.

Figure 7.1: Motifs of the $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ cluster minima.

For the $\mathrm{Lu}_{3} \mathrm{C}_{3}$ clusters, all minima structures possess doublet spin multiplicity. The lowest-energy $\mathrm{Lu}_{3} \mathrm{C}_{3}$ cluster correspond to the structure depicted in Figure 7.1d, followed by the 7.1 b structure, $0.73 \mathrm{kcal} / \mathrm{mol}$ higher in energy. As Table 7.2 shows, in the doublet $\mathrm{Lu}_{3} \mathrm{C}_{3}$

### 7.2. EMPTY FULLERENE CAGES: $\mathrm{C}_{104}$ AND $\mathrm{C}_{106}$

(d) ground state cluster, the shortest and longest Lu-C bond distances are 2.13 and $2.45 \AA$, respectively. Thus, they are large than the $\mathrm{Lu}-\mathrm{C}$ distances in the doublet $\mathrm{Lu}_{3} \mathrm{C}$ minimum.

### 7.2 Empty Fullerene Cages: $\mathrm{C}_{104}$ and $\mathrm{C}_{106}$

The theoretical challenge associated with the search of low-energy structures for large-sized fullerenes stems mainly from the rapid increase of the number of isomers with the fullerene size. For ab-initio density functional theory (DFT) calculations a large number of isomers translates into large computational cost. To overcome this so-called "million-isomer" problem, theoretical strategies have been adopted by several groups [296, 334-339]. In between these strategies the IPR rule is a common prescreening tool. It reduces dramatically the number of isomer candidates in the search. For example, the number of all possible isomers of $\mathrm{C}_{106}$ is 497529 whereas the number of IPR isomers is only 1233 . Unfortunately, even this number of isomers is still too large for conventional ab-initio methods. Therefore, energy prescreening with empirical force fields or semiempirical electronic structure methods is commonly used. In particular semiempirical methods are often employed due to their fast structure optimization and reasonable accurate relative energies. Based on an energy cutoff fullerene cage isomers from such semiempirical calculations are selected as candidates for subsequent ab-initio calculations [296, 334-339]. The combination of semiempirical and DFT calculations assumes that the energy ordering of the fullerene isomers is qualitatively similar at the different theoretical levels. This can be problematic. With the development of lower-order scaling hybrid DFT methods like auxiliary density functional theory (ADFT) and their efficient parallelization, this approach can now be extended to fullerenes with more than 100 atoms [340, 341].

In this part of the work we have optimized all neutral and hexaanionic IPR isomers of $\mathrm{C}_{104}$ and $\mathrm{C}_{106}$ employing the already validated methodology for the middle-sized fullerene calculations (see $\mathrm{C}_{80}$ fullerenes calculations in Chapter 5). Following this methodology, the ADFT composite approach consisting of PBE structure optimizations and PBE0 [273] single-point energy calculations was used [328]. For comparison with literature data we also performed
structure optimizations with the B3LYP functional and the 6-31G* Hartree-Fock optimized basis set [291, 342, 343]. Single-point energy calculations were also performed with the 6$311 G^{*}$ and aug-cc-pVTZ basis sets [344]. In order to determine the accuracy of our composite approach for large-sized fullerenes, we performed reference structure optimization for selected $\mathrm{C}_{106}$ fullerenes with the PBE0 and B3LYP hybrid functionals employing the aug-cc-pVTZ basis. To simplify the addressing of the fullerene isomers we order them according to their relative stability at the PBE/DZVP level of theory. Thus, the most stable isomer is number 1 , followed by the next stable one with number 2 and so. We also add in parenthesis the point group symmetry and canonical face spiral number. For example, the most stable neutral $\mathrm{C}_{104}$ isomer is named $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right)$ according to this nomenclature.

Table 7.3 lists the most stable $\mathrm{C}_{104}$ IPR isomers at the PBE/DZVP level of theory. The histogram in Figure 7.2 shows the energy distribution of all $\mathrm{C}_{104}$ IPR isomers at the PBE/DZVP level of theory. The $\mathrm{C}_{104}$ IPR isomers in the first 2 bins that span an energy range of $10 \mathrm{kcal} / \mathrm{mol}$ are the isomers given in Table 7.3. The complete table for all $\mathrm{C}_{104} \mathrm{IPR}$ isomers can be found in Appendix B. As Table 7.3 shows, all listed methodologies predict the same ground state for $\mathrm{C}_{104}$, namely the isomer $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right)$. To investigate the effect of van der Waals interactions on the relative energies we performed $\mathrm{PBE}+\mathrm{D}$ [311] single-point energy calculations on top of the PBE optimized structures. Although van der Waals interactions are of crucial importance for intermolecular interactions between fullerenes [345], they affect the relative energies of the $\mathrm{C}_{104}$ isomers only little $(\lesssim 0.5 \mathrm{kcal} / \mathrm{mol})$ as Table 7.3 shows. We can compare our GGA results directly with the ones published by Yang et al. [346]. Here all $\mathrm{C}_{104}$ IPR isomers were optimized with the semiempirical AM1 method and the 90 most stable isomers were calculated at the PBE/TZ2P level of theory. As Table 7.3 shows, the $\mathrm{PBE} / \mathrm{TZ2P} / /$ AM1 energy ordering of the first three isomers, i.e., $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right), \mathbf{2}\left(\mathrm{C}_{2}-443\right)$ and $3\left(\mathrm{C}_{2}-766\right)$, is in good quantitative agreement with that of our PBE/DZVP methodology. For higher energy isomers this agreement deteriorates. In particular, the PBE/TZ2P//AM1 isomer ordering of Yang et al. shows holes compared to our PBE/DZVP results listed in Table 7.3. We attribute this to the semiempirical prescreening used in reference [346].

Table 7.3 also shows that the use of hybrid functionals, here PBE0, has a significant effect

on the relative isomer energies as can be seen from the PBE0/DZVP//PBE/DZVP column of this table. To put our $\mathrm{C}_{104}$ hybrid calculations into perspective we compare them with results published by Shao et al. [335]. All IPR isomers in this study were optimized using the DFTB method. For the lowest DFTB isomers within an energy cutoff of $6.3 \mathrm{kcal} / \mathrm{mol}$, single-point energy calculations at the PBE0/6-311G* level of theory were performed. As Table 7.3 shows the isomer $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right)$ was also found as ground state in this study. Note that the same ground state is also found at the semiempirical DFTB and PM3 level of theory (column PM3 and DFTB in Table 7.3). However, for higher energy isomers the reported semiempirical relative energy ordering varies significantly from those of DFT calculations. Particularly interesting in this respect is the comparison of the DFTB and $\mathrm{PBE} 0 / 6-311 \mathrm{G}^{*} / / \mathrm{DFTB}$ relative energies. Although both calculations employ DFTB optimized $\mathrm{C}_{104}$ structures the relative energies of the isomers, except for the ground state, are very different. In particular, the low-energy isomer ordering at the PBE0/6-311G*//DFTB level of theory is in good qualitative agreement with that of our $\mathrm{PBE} 0 / \mathrm{DZVP} / / \mathrm{PBE} / \mathrm{DZVP}$ composite approach. However, the values of the relative energies are very different. Whereas in the work of Shao et al. a near energetical

Figure 7.2: Histogram of the relative energy distribution with bins of $5 \mathrm{kcal} / \mathrm{mol}$ for the neutral $\mathrm{C}_{104}$ IPR isomers.
degeneracy between the $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right)$ ground state and the $\mathbf{8}\left(\mathrm{D}_{2}-812\right)$ first excited state was found, our composite approach shows a much larger energy difference of around $4 \mathrm{kcal} / \mathrm{mol}$. As Table 7.3 shows this is a general trend, i.e. our PBE0/DZVP//PBE/DZVP composite approach yields larger relative energy differences than the reported PBE0/6-311G*//DFTB methodology. As a result, the $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{C}_{104}$ ground state is in our composite approach well separated from the excited states. This result provides also a natural explanation for the fact that all methodologies listed in Table 7.3 predict the same ground state. Experimentally, the $\mathrm{C}_{104}$ giant fullerene has been isolated in form of the chloro derivatives $\mathrm{C}_{104}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{Cl}_{16}$, $\mathrm{C}_{104}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{Cl}_{18}, \mathrm{C}_{104}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{Cl}_{20}$ and $\mathrm{C}_{104}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{Cl}_{22}$. Thus, the chlorination of HPLC fractions with pristine $\mathrm{C}_{104}$, followed by X-Ray crystallographic study, confirmed the presence of the theoretically predicted $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right) \mathrm{C}_{104}$ ground state, among others, in the soot [346, 347].

The relative energies of the low-lying hexaanionic $\mathrm{C}_{104}$ fullerenes are listed in Table 7.4. As this table shows all three theoretical methodologies used in this work, PBE/DZVP, $\mathrm{PBE}+\mathrm{D} / \mathrm{DZVP} / / \mathrm{PBE} / \mathrm{DZVP}$ and $\mathrm{PBE} / \mathrm{DZVP} / / \mathrm{PBE} / \mathrm{DZVP}$ yield the same energy or-

dering for the listed 10 isomers. In general, the relative energy separation between the hexaanionic isomers is larger as compared to the neutral $\mathrm{C}_{104}$ fullerenes. This can also be seen from the histogram of the relative energy distribution for the $\mathrm{C}_{104}^{6-}$ fullerenes given in Figure 7.3. We note that our $\mathrm{C}_{104}^{6-}$ ground state assignment is also in agreement with the one from Rodríguez-Fortea et al. [348] at the AM1 level of theory. In conclusion, our study of the $\mathrm{C}_{104}$ and $\mathrm{C}_{104}^{6-}$ fullerenes reveals ground states, namely $\mathbf{1}\left(\mathrm{C}_{\mathrm{s}}-234\right)$ and $\mathbf{1}\left(\mathrm{D}_{2}-821\right)$, that are at the PBE0/DZVP / $\mathrm{PBE} / \mathrm{DZVP}$ level of theory energetically well separated from other low-lying isomers.

Table 7.5 lists the twenty two most stable neutral $\mathrm{C}_{106}$ IPR isomers ordered according to their relative $\mathrm{PBE} / \mathrm{DZVP}$ energies. As the histogram in Figure 7.4 shows, $\mathrm{C}_{106}$ possess a dense low-lying energy isomer distribution with almost 80 isomers in a $10 \mathrm{kcal} / \mathrm{mol}$ energy range. Because our focus is on the energetically most stable isomers and in order to compare our data with those reported in [339], we will only discuss the 22 isomers listed in Table 7.5. The complete data set for the neutral $\mathrm{C}_{106}$ IPR isomers can be found in Appendix B of this work. Table 7.5 shows that empirical dispersion corrections have also for $\mathrm{C}_{106}$ only little effect on the relative energies of the isomers. However, as already seen for the neutral and anionic $\mathrm{C}_{104}$ fullerenes, hybrid functionals change the relative energy ordering considerably. Different to the $\mathrm{C}_{104}$ fullerenes the assignment of the $\mathrm{C}_{106}$ ground state varies for different theoretical

Figure 7.3: Histogram of the relative energy distribution with bins of $5 \mathrm{kcal} / \mathrm{mol}$ for the hexaanionic $\mathrm{C}_{104}$ IPR isomers.
approaches due to the small relative energy differences. In our PBE0/DZVP//PBE/DZVP composite approach we find as ground state the $\mathbf{7}\left(\mathrm{C}_{\mathrm{s}}-331\right)$ isomer followed by the $\mathbf{4}\left(\mathrm{C}_{2}-1194\right)$ and $1\left(\mathrm{C}_{1}-534\right)$ isomers that are energetically degenerated and $1 \mathrm{kcal} / \mathrm{mol}$ above the ground state. A similar qualitative picture is obtained by Shao et al. [335] with the PBE0/6$311 G^{*} / /$ DFTB approach and by Wang et al. [339] with the B3LYP/6-311G*//B3LYP/6$31 G^{*}$ approach, respectively. Note, however, that Wang et al. obtained with the B3LYP/6$31 G^{*} / / B 3 L Y P / 3-21 G^{*}$ a different ground state assignment, namely $C_{106} 4\left(\mathrm{C}_{2}-1194\right)$ instead of $\mathbf{7}\left(\mathrm{C}_{\mathrm{s}}-331\right)$.

To gain further insight into the reliability of these results we also performed B3LYP/6$31 G^{*}$, B3LYP/6-311G*//B3LYP/6-31G* and B3LYP/aug-cc-pVTZ//B3LYP/6-31G* calculations of the $\mathrm{C}_{106}$ fullerenes listed in Table 7.5. As the comparison of these hybrid calculations shows the ground state assignment for the $\mathrm{C}_{106}$ fullerene varies with the used hybrid functional and basis set. Although an unequivocal assignment of the $\mathrm{C}_{106}$ ground state is not possible from these results, all our hybrid functional calculations indicate that the three lowest $\mathrm{C}_{106}$ isomers are $\mathbf{1}\left(\mathrm{C}_{1}-534\right), \mathbf{4}\left(\mathrm{C}_{2}-1194\right)$ and $\mathbf{7}\left(\mathrm{C}_{\mathrm{s}}-331\right)$. The energy separation of these

### 7.2. EMPTY FULLERENE CAGES: $\mathrm{C}_{104}$ AND $\mathrm{C}_{106}$

Figure 7.4: Histogram of the relative energy distribution with bins of $5 \mathrm{kcal} / \mathrm{mol}$ for the neutral $\mathrm{C}_{106}$ IPR isomers.
isomers is within $1 \mathrm{kcal} / \mathrm{mol}$. In order to compare our different hybrid calculations quantitatively we have correlated them in Figure 7.5 against each other. In Figure 7.5a, 7.5b and 7.5 c are plotted the relative energies of the 22 isomers of Table 7.5 obtained with the B3LYP/6-31G*, B3LYP/6-311G*//B3LYP/6-31G* and B3LYP/aug-cc-pVTZ//B3LYP/631G* methods against the relative energies of the PBE0/DZVP//PBE/DZVP composite approach. As these three graphs shows, the best correlation with a linear correlation coefficient of $r=0.984$ is obtained between the B3LYP/6-311G*//B3LYP/6-31G* methodology and the PBE0/DZVP//PBE/DZVP composite approach. The corresponding maximum absolute deviation (MAX) and mean absolute deviation (MAD) are 1.1 and $0.6 \mathrm{kcal} / \mathrm{mol}$, respectively. This indicates that the PBE0/DZVP//PBE/DZVP composite approach yields relative energies for $\mathrm{C}_{106}$ fullerenes that are within $1 \mathrm{kcal} / \mathrm{mol}$ identical to the $\mathrm{B} 3 \mathrm{LYP} / 6$ -311G*//B3LYP/6-31G* methodology. Because the composite approach uses GGA optimized structures and DZVP basis sets in the single-point hybrid energy calculations it can be efficiently used to scan large numbers of fullerene isomers. For the other correlations in Figure 7.5, namely B3LYP/6-31G* (Figure 7.5a) and B3LYP/aug-cc-pVTZ//B3LYP/6-31G*
Table 7.5: Relative energies [kcal/mol] of the $\mathrm{C}_{106}$ fullerene cages as obtained from different theoretical methodologies.

### 7.2. EMPTY FULLERENE CAGES: $\mathrm{C}_{104}$ AND $\mathrm{C}_{106}$

(Figure 7.5c) vs PBE0/DZVP//PBE/DZVP we find MAX values of 1.3 and $1.5 \mathrm{kcal} / \mathrm{mol}$ and MAD values of 0.7 and $0.9 \mathrm{kcal} / \mathrm{mol}$, respectively.

Figure 7.5: $\mathrm{C}_{106}$ relative energy [kcal/mol] correlation plots of B3LYP/6-31G* (a), B3LYP/ 6-311G*//B3LYP/6-31G* (b) and B3LYP/aug-cc-pVTZ//B3LYP/6-31G* (c) vs PBE0/DZVP// PBE/DZVP. (d) Correlation between the relative energies from four-center ERI DFT and threecenter ERI ADFT calculations at the B3LYP/6-311G*//B3LYP/6-31G* level of theory. In all graphs the solid line represents the linear fit of the corresponding data set.

All graphs in Figure 7.5 show a systematic shift of 0.5 to $1 \mathrm{kcal} / \mathrm{mol}$ of the PBE0 relative energies with respect to the B3LYP ones. This suggests an intrinsic hybrid functional dependency of the $\mathrm{C}_{106}$ relative energies. To investigate this in more detail we fully optimized the three energetically lowest lying $\mathrm{C}_{106}$ isomers at the PBE0/aug-cc-pVTZ and B3LYP/aug-ccpVTZ level of theory. Table 7.6 lists the obtained relative energies from these calculations. As this table shows the ground state assignment for the $\mathrm{C}_{106}$ fullerene is different for the PBE0 and B3LYP hybrid functional. Whereas isomer $7\left(\mathrm{C}_{\mathrm{s}}-331\right)$ is found as ground state

Table 7.6: Relative energies [kcal/mol] of the energetically three lowest lying $\mathrm{C}_{106}$ isomers optimized at the specified level of theory.

| Isomer | PBE0/aug-cc-pVTZ | B3LYP/aug-cc-pVTZ |
| :--- | :---: | :---: |
| $1\left(\mathrm{C}_{1}-534\right)$ | 0.7 | 0.3 |
| $4\left(\mathrm{C}_{2}-1194\right)$ | 0.6 | $\mathbf{0 . 0}$ |
| $7\left(\mathrm{C}_{\mathrm{s}}-331\right)$ | $\mathbf{0 . 0}$ | 0.2 |

with PBE0/aug-cc-pVTZ, isomer $4\left(\mathrm{C}_{2}-1194\right)$ is found as ground state with B3LYP/aug-ccpVTZ. Also the energy separation between the ground state and the energetically low-lying isomers is larger with PBE0 than with B3LYP. This confirms the general observation from the linear correlation plots in Figure 7.5.

Comparing the PBE0/aug-cc-pVTZ isomer ordering from Table 7.6 with other PBE0 results from Table 7.5, a consistent ground state assignment of isomer $7\left(\mathrm{C}_{\mathrm{s}}-331\right)$ is found. This situation is different for the B3LYP results. As can be seen from Table 7.5 and 7.6 all three low-lying isomers, i.e. $\mathbf{1}\left(\mathrm{C}_{1}-534\right), \mathbf{4}\left(\mathrm{C}_{2}-1194\right)$ and $\mathbf{7}\left(\mathrm{C}_{\mathrm{s}}-331\right)$, are assigned as ground states by the different B3LYP calculations. The reason is the much smaller energy splitting between these isomers in the B3LYP calculations. Altogether, our results on the $\mathrm{C}_{106}$ fullerene reveal three low-lying isomers within an energy range of around $1 \mathrm{kcal} / \mathrm{mol}$. In order to study the effect of the hybrid functionals on the optimized structure parameters we performed similarity analyses [310] between the PBE/DZVP optimized $\mathbf{1}\left(\mathrm{C}_{1}-534\right), \mathbf{4}\left(\mathrm{C}_{2}-1194\right)$ and $\mathbf{7}\left(\mathrm{C}_{\mathrm{s}^{-}}\right.$ 331) structures and their PBE0/aug-cc-pVTZ and B3LYP/aug-cc-pVTZ counterparts. The obtained similarity indices of 0.994 and 0.996 , respectively, indicate almost perfect (similarity index of 1) geometrical agreement between these optimized structures.

The dense low-lying energy isomer distribution of $\mathrm{C}_{106}$ (see Figure 7.4) also permits a quantitative assessment of the here used four-center ERI free hybrid ADFT approach. To this end we have plotted in Figure 7.5d the four-center ERI Kohn-Sham DFT B3LYP/6-311G*//B3LYP/6-31G* $\mathrm{C}_{106}$ relative energies against their ADFT counterparts. The fourcenter ERI Kohn-Sham relative energy data points in Figure 7.5d are taken from Wang et al. [339] as listed in Table 7.5. As Figure 7.5d shows an excellent correlation $(r=0.995)$ between the two methodologies is obtained. The MAD of $0.1 \mathrm{kcal} / \mathrm{mol}$ and the MAX of $0.2 \mathrm{kcal} / \mathrm{mol}$

### 7.2. EMPTY FULLERENE CAGES: $\mathrm{C}_{104}$ AND $\mathrm{C}_{106}$

are one order of magnitude smaller than the intrinsic accuracy of the B3LYP functional. This result shows that four-center ERI free hybrid ADFT calculations are an accurate, reliable and computationally much less demanding alternative to conventional Kohn-Sham calculations for the ground state assignment of large fullerenes.

Table 7.7 lists the ten most stable hexaanionic $\mathrm{C}_{106}$ IPR isomers ordered according to their relative PBE/DZVP energies. Unlike the neutral $\mathrm{C}_{106}$ fullerenes, the hexaanionic $\mathrm{C}_{106}$ ground state, $\mathbf{1}\left(\mathrm{C}_{2}-891\right)$, is energetically well separated from the other isomers.

Table 7.7: Relative energies [kcal/mol] of the anionic $\mathrm{C}_{106}^{6-}$ fullerene cages as obtained from different theoretical methodologies.

| Isomer | $\mathrm{PBE} / \mathrm{DZVP} / /$ <br> $\mathrm{PBE} / \mathrm{DZVP}$ | $\mathrm{PBE}+\mathrm{D} / \mathrm{DZVP} / /$ <br> $\mathrm{PBE} / \mathrm{DZVP}$ | $\mathrm{PBE} / \mathrm{DZVP} / /$ <br> $\mathrm{PBE} / \mathrm{DZVP}$ |
| :--- | :---: | :---: | :---: |
| $1\left(\mathrm{C}_{2}-891\right)$ | $\mathbf{0 . 0}$ | $\mathbf{0 . 0}$ | $\mathbf{0 . 0}$ |
| $2\left(\mathrm{C}_{1}-747\right)$ | 5.2 | 5.3 | 6.2 |
| $3\left(\mathrm{C}_{1}-896\right)$ | 5.9 | 5.9 | 6.6 |
| $4\left(\mathrm{C}_{1}-974\right)$ | 6.7 | 6.9 | 7.5 |
| $5\left(\mathrm{C}_{1}-724\right)$ | 7.0 | 6.7 | 7.4 |
| $6\left(\mathrm{C}_{1}-735\right)$ | 7.4 | 7.4 | 8.8 |
| $7\left(\mathrm{C}_{1}-1080\right)$ | 8.2 | 7.9 | 9.1 |
| $8\left(\mathrm{C}_{2}-970\right)$ | 9.3 | 9.4 | 10.3 |
| $9\left(\mathrm{C}_{1}-725\right)$ | 10.7 | 10.5 | 11.3 |
| $10\left(\mathrm{C}_{1}-740\right)$ | 10.7 | 10.6 | 12.0 |

As Table 7.7 shows all three theoretical methodologies used in this work, PBE/DZVP, $\mathrm{PBE}+\mathrm{D} / \mathrm{DZVP} / / \mathrm{PBE} / \mathrm{DZVP}$ and PBE0/DZVP//PBE/DZVP show the same energy ordering for the listed 10 isomers. The reason is the energy separation between the hexaanionic isomers, which is quite large in comparison to the neutral $\mathrm{C}_{106}$ fullerenes. This can also be seen from the histograms of the relative energy distribution for $\mathrm{C}_{106}$ and $\mathrm{C}_{106}^{6-}$ given in Figure 7.4 and 7.6 , respectively. They differ significantly in the first two bins. For the case of neutral isomers, the number of structures in a $10 \mathrm{kcal} /$ mol energy window is more than 50 , while for the hexaanionic only 8 structures are within that energy window.

Figure 7.6: Histogram of the relative energy distribution with bins of $5 \mathrm{kcal} / \mathrm{mol}$ for the hexaanionic $\mathrm{C}_{106}$ IPR isomers.

### 7.3 Structure Elucidation of the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ System

In this final step we enclosed the $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ minima structures in the $\mathrm{D}_{2}-821, \mathrm{D}_{3 \mathrm{~d}}-822$, $\mathrm{C}_{2}-816, \mathrm{C}_{2}-553$ and $\mathrm{C}_{2}-706$ isomers of the $\mathrm{C}_{104}$ and in the $\mathrm{C}_{2}-891, \mathrm{C}_{1}-747, \mathrm{C}_{1}-896, \mathrm{C}_{1}-974, \mathrm{C}_{1}-$ $724, \mathrm{C}_{1}-735$ and $\mathrm{C}_{1}-1080$ isomers of the $\mathrm{C}_{106}$ fullerene cages, respectively. These $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ and $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106} \text { starting structures, were optimized on the corresponding doublet and quartet }}^{\text {s }}$ potential energy surface. Table 7.8 lists the relative energies of $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ endohedral fullerene structures. As this Table shows, two EMF structures are very closed in energy, the lowest-energy structure is an EMF with $\mathrm{Lu}_{3} \mathrm{C}$ cluster inside the $\mathrm{C}_{106}\left(\mathrm{C}_{1}-735\right)$ IPR isomer. At only $0.80 \mathrm{kcal} / \mathrm{mol}$ above this EMF, another structure formed by $\mathrm{Lu}_{3} \mathrm{C}_{3}$ cluster inside the $\mathrm{C}_{104}\left(\mathrm{D}_{2}-821\right)$ IPR isomer, is found. These two structures have a doublet spin multiplicity. Figure 7.7 shows the three most stable $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ EMF structures.

### 7.3. STRUCTURE ELUCIDATION OF THE $L_{3} \mathrm{C}_{107}$ SYSTEM

 structures.

| $\mathrm{C}_{106}$ isomer | Multiplicity | $\Delta \mathrm{E}$ <br> $[\mathrm{kcal} / \mathrm{mol}]$ | $\mathrm{C}_{104} \mathrm{isomer}$ | Multiplicity | $\Delta \mathrm{E}$ <br> $[\mathrm{kcal} / \mathrm{mol}]$ | $\Delta \mathrm{E}_{\mathrm{C}_{106}}^{a}$ <br> $[\mathrm{kcal} / \mathrm{mol}]$ |
| :--- | :---: | :---: | :--- | :---: | :---: | :---: |
| $\mathrm{C}_{1}-735$ | 2 | $\mathbf{0 . 0 0}$ | $\mathrm{D}_{2}-821$ | 2 | 0.00 | 0.80 |
| $\mathrm{C}_{1}-735$ | 4 | 23.31 | $\mathrm{D}_{2}-821$ | 4 | 22.42 | 23.18 |
| $\mathrm{C}_{2}-891$ | 2 | 2.50 | $\mathrm{D}_{3 \mathrm{~d}}-822$ | 2 | 4.95 | 5.71 |
| $\mathrm{C}_{2}-891$ | 4 | 24.82 | $\mathrm{D}_{3 \mathrm{~d}}-822$ | 4 | 19.70 | 20.42 |
| $\mathrm{C}_{1}-896$ | 2 | 4.50 | $\mathrm{C}_{2}-706$ | 2 | 6.45 | 7.21 |
| $\mathrm{C}_{1}-896$ | 4 | 29.60 | $\mathrm{C}_{2}-706$ | 4 | 24.50 | 25.23 |
| $\mathrm{C}_{1}-747$ | 2 | 10.10 | $\mathrm{C}_{2}-816$ | 2 | 10.10 | 10.83 |
| $\mathrm{C}_{1}-747$ | 4 | 32.30 | $\mathrm{C}_{2}-816$ | 4 | 28.13 | 28.90 |
| $\mathrm{C}_{1}-1080$ | 2 | 11.34 | $\mathrm{C}_{2}-553$ | 2 | 12.30 | 13.05 |
| $\mathrm{C}_{1}-1080$ | 4 | 30.64 | $\mathrm{C}_{2}-553$ | 4 | 28.40 | 29.20 |
| $\mathrm{C}_{1}-974$ | 2 | 12.62 |  |  |  |  |
| $\mathrm{C}_{1}-974$ | 4 | 28.64 |  |  |  |  |
| $\mathrm{C}_{1}-724$ | 2 | 13.00 |  |  |  |  |
| $\mathrm{C}_{1}-724$ | 4 | 31.80 |  |  |  |  |

${ }^{a}$ Relative energies of $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ structures with respect to the lowest-energy $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106} \text { structure. }}$

Figure 7.7: Optimized six lowest-energy structures for $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ endohedral fullerenes.

In the three $\mathrm{Lu}_{3} \mathrm{C} @ \mathrm{C}_{106}$ most stable structures, each Lu atoms is situated over a $[5,6]$ bond (the bond shared by a pentagon and a hexagon). While for the three $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ most stable structures, the metal ions are located above of a carbon atom which connects a pentagon and two hexagons $[5,6,6]$. Therefore, we can conclude that for the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ EMF system, there are two possible structures, the $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}^{\left(\mathrm{C}_{1}-735\right) \text { and the } \mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}\left(\mathrm{D}_{2}-821\right) \text { EMFs. }}$

## Chapter 8

## Conclusions and Perspectives

### 8.1 Conclusions

This thesis develops the study of endohedral metallofullerenes containing lanthanides and actinides employing the linear combination of Gaussian-type orbital density functional theory (LCGTO-DFT) as implemented in the deMon2k program. Isolation and characterization of endohedral fullerenes suffers from low synthetic yields and difficult purification processes. In this respect, we utilized theoretical methods to elucidate the structure of $\mathrm{U}_{2} \mathrm{C}_{79}[26,27]$ and $\mathrm{Lu}_{3} \mathrm{C}_{107}$ [28] endohedral metallofullerenes, observed by mass spectrometric analysis.

In summary, after the analysis and understanding of the most important features that govern the stability of endohedral metallofullerenes we designed an efficient computational strategy for their structure elucidation. This computational protocol is step-by-step validated by the structural elucidation of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF. To this end, the uranium atom, uranium dimer, neutral and anionic $\mathrm{C}_{80}$ fullerene cages as well as the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF system were studied. The calculations of the uranium dimer showed that GEN-A2* auxiliary function sets are insufficient for the accurate description of lanthanide and actinide compounds. To overcome this drawback the extended GEN-An** auxiliary function set was developed within this thesis. The uranium atom and dimer calculations also revealed that ADFT and KS-DFT results become consistent to each other, when the extended GEN-An** auxiliary function set
is employed for lanthanides and actinides. Using the extended GEN-A2** auxiliary function set for uranium the GGA uranium dimer calculations predict consistently a septet ground state spin multiplicity, in agreement with other theoretical studies. However, our calculated $2.30[\AA]$ U-U bond length is considerable shorter according to the reported 2.43 [286], 2.56 [288] and $3.0[\AA]$ [284] bond distances. With our GGA methodologies, the dissociation energy tend to be overestimated severely, compared to the experimental and theoretical reported values available up to now. Suggesting with the above, that other methodologies or approaches should be analyzed in order to improve the description of this heavy element. In order to improve these dissociation energy values, single-point energy calculations with global and range-separated hybrid functionals on top of the PBE optimized structures, were performed. Obtaining as a result significantly reduction in the dissociation energy values. In particularly, with the range-separated CAMB3LYP hybrid functional dissociation energies in the same range as from multiconfigurational wave function methods, are obtained.

The study of the seven IPR isomers of the $\mathrm{C}_{80}$ fullerene cage, reveals the $\mathrm{D}_{2}-2$ and $\mathrm{D}_{5 \mathrm{~d}}-1$ structures as the two energetically lowest-lying isomers. From these calculations we found that our GGA optimized structures are almost indistinguishable from those optimized with hybrid functionals. In fact, employing our PBE0/DZVP//PBE/DZVP ADFT composite approach [328], consisting of GGA structure optimizations and hybrid single-point energy calculations, yields results that are in agreement with those reported in the literature for hybrid functionals [300, 349]. However, an important difference between the here proposed composite approach and similar hybrid functional based approaches from the literature is that we employ GGA rather than hybrid structure optimizations. As a result, the PBE0/DZVP//PBE/DZVP composite approach can be used to screen much larger number of higher fullerene structures without jeopardizing reliability.

A ADFT study of $\mathrm{U}_{2}$ inside the $\mathrm{C}_{80}\left(\mathrm{I}_{\mathrm{h}}-7\right)$ isomer has been carried out, and our results predict two low-lying structures, a $\mathrm{D}_{2 \mathrm{~h}}$ and a $\mathrm{C}_{\mathrm{i}}$ symmetric $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMFs, both with septet spin multiplicity. An isomer very close to the $\mathrm{D}_{2 \mathrm{~h}}$ configuration, was recently experimentally reported to be the lowest in energy [25]. Our two minimum structures together with the transition state structure are very closed in energy, indicating a flat potential energy

### 8.1. CONCLUSIONS

surface of the $\mathrm{U}_{2} @ \mathrm{C}_{80}$ EMF system, allowing thus, the U movement from one configuration to another without a significant barrier. This is in good agreement with the disorder of U atoms observed crystallographically [25]. The electronic structure analysis reveals that the charge transfer from the uranium to the $\mathrm{C}_{80}$ cage is localized at the coordination sites, which in turn elongates the corresponding C-C bonds due to electrostatic repulsion. From the IR and Raman spectra we can conclude the following important aspects. The IR spectra of the two minima structures are very similar throughout the frequency range. Moreover, the translational-like IR active modes are so weak that they are barely visible. Thus, on the basis of these IR spectra alone, it is hard to distinguish one structure from another. On the other hand, the Raman spectra could distinguish experimentally one isomer from the other. The degenerated peak corresponding to the rotational-like U-U modes in the $\mathrm{D}_{2 \mathrm{~h}}$ EMF $\left(\mathrm{S}_{1}\right)$ has a stronger intensity compared to the two non-degenerated peaks in the $\mathrm{C}_{\mathrm{i}}$ EMF $\left(\mathrm{S}_{2}\right)$. Additionally, the simulated Raman spectra are able to reproduce the most important features of the experimental spectrum (which is reported in a low-energy range, from 100 to $600 \mathrm{~cm}^{-1}$ ) in the range between 120 and $230 \mathrm{~cm}^{-1}$.

Based on the validated computational strategy and methodology we performed calculations in order to elucidate the structure of the $\mathrm{U}_{2} \mathrm{C}_{79}$ EMF system, synthesized in Dr. Echegoyen's research group [26, 27]. From these calculations we conclude that the experimentally observed $\mathrm{U}_{2} \mathrm{C}_{79}$, is in fact a $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}}^{\text {structure. The symmetry of the synthesized }}$ cage is assigned to the $\mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ isomer. From an iterative Hirshfeld population analysis, we assume that four electrons are donated from the $\mathrm{U}_{2} \mathrm{C}$ cluster to the carbon cage, assigning the electronic structure of this EMF as $\left(\mathrm{U}_{2} \mathrm{C}\right)^{4+} @ \mathrm{C}_{78}{ }^{4-}$. The $\mathrm{U}_{2} \mathrm{C}$ cluster has a linear structure inside the cage in order to minimize the electrostatic repulsion between the two uranium atoms. The ground state structure has triplet spin multiplicity, with optimized U-C bond length of $2.04 \AA$. In this context it is important to note that in a recent theoretical study [21] a triplet ground state for $U_{2}{\mathrm{C} @ \mathrm{C}_{78}}$ was predicted, too. However, in this study the $\mathrm{U}_{2} \mathrm{C}$ cluster was reported bended with a bond angle of $123.9^{\circ}$ and $\mathrm{U}-\mathrm{C}$ bond length of 2.01 $[\AA]$. Moreover, the electronic structure of $\mathrm{U}_{2}{\mathrm{C} @ \mathrm{C}_{78}}$ was assigned to $\left(\mathrm{U}_{2} \mathrm{C}\right)^{6+} @ \mathrm{C}_{78}{ }^{6-}$ rather than $\left(\mathrm{U}_{2} \mathrm{C}\right)^{4+} @ \mathrm{C}_{78}{ }^{4-}$. The differences in these results were investigated and calculations
show that our $\mathrm{U}_{2} \mathrm{C} @ \mathrm{C}_{78}\left(\mathrm{D}_{3 \mathrm{~h}}-24109\right)$ minimum structure with a linear $\mathrm{U}_{2} \mathrm{C}$ unit is lower in energy than the one reported in literature [21] at all relevant levels of theory. Additionally, to guide future experiments, we also present the IR and Raman spectra of this EMF.

In the last part of the thesis a study of the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ EMF system observed by mass spectrometry [28], was carried out based on the assumption that this EMF with an odd number of carbon atoms is either a $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ or $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}}$ carbide clusterfullerene. For this study, calculations to the lutetium dimer as well as of the $\mathrm{C}_{104}$ and $\mathrm{C}_{106}$ fullerene cages were performed with the purpose to elucidate the best methodology for this system. The calculations show that the QECP43 pseudopotential and its corresponding valence basis set predict results that are in agreement with available experimental and high-level ab-initio data. Subsequently, the free $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ motifs were optimized. For both systems doublet ground state structures were assigned on the basis of these calculations. Employing our composite approach the ground states for the neutral and hexaanionic $\mathrm{C}_{104}$ fullerene cages were predicted as the $\mathrm{C}_{\mathrm{s}}-234$ and $\mathrm{D}_{2}$-821 isomers, respectively. These findings are in agreement with previous reports in the literature.[335, 348] For the neutral $\mathrm{C}_{106}$ several calculations were performed and the results show that the ground state assignment for this fullerene cage varies with the used hybrid functional and basis set. Altogether, our hybrid calculations on the $\mathrm{C}_{106}$ fullerene reveal three low-lying isomers, $\mathrm{C}_{\mathrm{s}}-331, \mathrm{C}_{2}-1194$ and $\mathrm{C}_{1}-534$. Their energy separation is less than $1 \mathrm{kcal} / \mathrm{mol}$. On the other hand, calculations for the hexaanionic $\mathrm{C}_{106}$ fullerene cages show a ground state $\mathrm{C}_{2}-891$ isomer well separated from the others which therefore, can be unequivocally assigned. We show with the extensive study of the IPR isomers of $\mathrm{C}_{104}$ and $\mathrm{C}_{106}$ that the PBE0/DZVP//PBE/DZVP ADFT composite calculations can be used to scan a large number of isomers. Moreover, accurate and reliable relative energies can be obtained, not only for middle-sized (as it was shown for the $\mathrm{C}_{80}$ ), but also for large-sized fullerenes. The computational performance of the ADFT composite approach is rooted in the variational fitting of the Coulomb and Fock potential. The obtained four-center ERI free ADFT hybrid approach yields energies and optimized structure parameters that are indistinguishable from those of their four-center counterparts. We have demonstrated this here on the B3LYP/6-311G*//B3LYP/6-31G* $\mathrm{C}_{106}$ relative energies. The resulting MAD and MAX

### 8.2. PERSPECTIVES

of 0.1 and $0.2 \mathrm{kcal} / \mathrm{mol}$, respectively, are one order of magnitude smaller than the intrinsic accuracy of the B3LYP functional. This underlines the accuracy of our four-center ERI free hybrid ADFT methodology [328]. Finally, our $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}$ and $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106} \text { calculations, }}$ reveal two low-lying structures with doublet spin multiplicity, the $\mathrm{Lu}_{3}{\mathrm{C} @ \mathrm{C}_{106}\left(\mathrm{C}_{1}-735\right) \text { and }}^{\text {a }}$ $\mathrm{Lu}_{3} \mathrm{C}_{3} @ \mathrm{C}_{104}\left(\mathrm{D}_{2}-821\right)$, within an energy window of around $0.80 \mathrm{kcal} / \mathrm{mol}$.

### 8.2 Perspectives

There are studies that can be performed to build on and complement the conclusions presented in the previous section. This research work gave some basic information, which is useful for further experimental and theoretical research works of endohedral metallofullerenes.

It will be interesting to apply the here proposed composite approach methodology to others endohedral lanthanides and actinides metallofullerenes. In addition, a systematic development of appropriate auxiliary function sets for lanthanide and actinide elements is desirable.

Theoretical treatments of actinide-containing molecules still present a challenge to the quantum chemist. The electronic structures of these molecules are unusually complicated, since both correlation and relativistic effects are large, and there may be significant coupling between them. In this respect, approximations such as the addition of a Hubbard term to the Hamiltonian (DFT +U ) have been developed in order to improve the description of the ground state of correlated systems [350-352]. In this respect, there is a great room of development and implementation for theoretical methodologies that can perform better treatment for the correlation and relativistic effects, that could improve the current results.

There is little reported information regarding the $\mathrm{U}_{2} \mathrm{C}_{x}$ and $\mathrm{Lu}_{3} \mathrm{C}_{x}(x=1,3)$ clusters. Therefore, extended theoretical studies in such systems would be of great relevance. BOMD simulations were carried out throughout this thesis work with the objective to explore different orientations and geometries that the endohedral cluster could adopt inside the fullerene cage. In this way, the calculation of the BOMD simulations, in order to explore and analyze different geometries and orientations that the $\mathrm{Lu}_{3} \mathrm{C}$ and $\mathrm{Lu}_{3} \mathrm{C}_{3}$ clusters can adopt inside the
$\mathrm{C}_{106}$ and $\mathrm{C}_{104}$ carbon cages, respectively, are highly recommended. Likewise, future calculations for a complete structure elucidation of the $\mathrm{Lu}_{3} \mathrm{C}_{107}$ EMF system are also desirable.

## Appendix A

## Tables of Relative Energies for the Empty $\mathrm{C}_{78}$ Fullerene Cages

The structures of 5 IPR isomers, 18 isomers with 1 APP and 228 isomers with 2 APP (APP: number of adjacent pentagon pairs) of the $\mathrm{C}_{78}$ fullerene cage were optimized employing the PBE/DZVP/GEN-A2* methodology. The tables show the order of these isomers according to their relative stability at the PBE/DZVP level of theory. To be compatible with the nomenclature used in this thesis, we also add in the label column the point group symmetry and isomer number according to the spiral algorithm.

Table A.1: Isomer enumeration according to their relative PBE/DZVP energies ( $\Delta \mathrm{E}$, in $\mathrm{kcal} / \mathrm{mol}$ ) of the diaanionic $\mathrm{C}_{78}$ fullerene cages and their corresponding labels as reported by Fowler et al [29].

## Appendix B

## Tables of the Relative Energies for the $\mathrm{C}_{104}$ and $\mathrm{C}_{106}$ IPR Isomers

The structures of $823 \mathrm{C}_{104}$ and $1233 \mathrm{C}_{106}$ IPR fullerene isomers were optimized employing the PBE/DZVP/GEN-A2* methodology. The tables show the order of these isomers according to their relative stability at the $\mathrm{PBE} / \mathrm{DZVP} / \mathrm{GEN}-\mathrm{A} 2^{*}$ level of theory. To be compatible with the nomenclature used in this thesis, we also add in the label column the point group symmetry and isomer number according to the spiral algorithm.

## APPENDIX B. RELATIVE ENERGIES FOR THE C ${ }_{104}$ AND C $\mathrm{C}_{106}$

Table B.1: Isomer numeration according to their relative PBE/DZVP energies ( $\Delta \mathrm{E}[\mathrm{kcal} / \mathrm{mol}]$ ) of the neutral $\mathrm{C}_{104}$ IPR fullerene cages and their corresponding labels as reported by Fowler et al. [29].

## APPENDIX B. RELATIVE ENERGIES FOR THE $\mathrm{C}_{104}$ AND $\mathrm{C}_{106}$

Table B. 3 (Cont.): Isomer numeration according to their relative PBE/DZVP energies ( $\Delta \mathrm{E}[\mathrm{kcal} /-$ $\mathrm{mol}]$ ) of the neutral $\mathrm{C}_{106}$ IPR fullerene cages and their corresponding labels as reported by Fowler et al. [29].

| No. | Label [29] | $\Delta \mathrm{E}$ | No. | Label [29] | $\Delta \mathrm{E}$ | No. | Label [29] | $\Delta \mathrm{E}$ | No. | Label [29] | $\Delta \mathrm{E}$ | No. | Label [29] | $\Delta \mathrm{E}$ |
